RECORDING MEDIUM, RECORDING METHOD, REPRODUCTION APPARATUS  
AND METHOD, AND COMPUTER-READABLE PROGRAM

5

### Technical Field

The present invention relates to a recording medium on which a digital stream generated by multiplexing a video stream and a graphics stream is recorded, and a reproduction apparatus for reproducing the digital stream. In particular, the present invention relates to techniques whereby the reproduction apparatus separately decodes the video stream and the graphics stream and overlays resulting video and graphics to produce a reproduction image.

15

### Background Art

Video/graphics overlay techniques mentioned above enable to select graphics and display the selected graphics in accordance with a language setting or display setting of a reproduction apparatus. Also, the video/graphics overlay techniques enable to select whether or not to display graphics according to need. Because of their capability of offering such selections, the video/graphics overlay techniques are employed in player models of DVD-Video and ETSI EN 300 743. In these standards, the graphics stream is an arrangement of PES packets. The PES packets can be classified into two types: a PES packet carrying control information and a PES packet carrying graphics data which represents graphics. The

control information is arranged before the graphics data, and one pair of control information and graphics data produces one graphics display. In more detail, the reproduction apparatus reads the control information and the graphics data  
5 in sequence, decodes the control information, and also decodes the graphics data to generate uncompressed graphics. The reproduction apparatus displays the uncompressed graphics with a desired presentation timing, according to a decoding result of the control information.

10         According to this technique, decoding of graphics data needs to be performed for each graphics display. This being so, a time interval from one graphics display to the next graphics display depends on a time period required for a decoding process of graphics data. If graphics has a higher  
15 resolution and a decoding process of graphics data takes a longer time, a time interval with which graphics is updated lengthens.

       In the case of subtitling in a movie film or the like where graphics is updated with a time interval of 2 to 3 seconds,  
20 proper graphics displays can still be produced even if graphics has a higher resolution and decoding of graphics data takes a longer time. In the case where graphics is used specially as a means of amusement, however, the need to shorten the graphics update interval arises.

25         For example, the use of graphics for amusement purposes includes such applications where graphics representing a dialog of a character is moved to attract the viewer's attention or varied in color to surprise the viewer. Producers of video

content such as variety shows are especially eager to adopt such graphics displays.

To realize smooth movements of graphics, however, an operation of decoding graphics data and presenting graphics  
5 needs to be performed within a short time of one frame period (1/29.97 seconds in NTSC). Repeating this operation of decoding graphics data and presenting graphics within each frame period requires a tremendous load, and is hard to be realized with hardware specifications of reproduction  
10 apparatuses that are expected to be provided at low cost.

The aforementioned graphics movements and variations in color can be achieved by overlaying graphics on each frame of video beforehand so that graphics forms a part of a picture pattern of each frame. This method of overlaying graphics  
15 on each frame beforehand, however, lacks flexibility of being able to selectively display graphics in accordance with a language setting or display setting of a reproduction apparatus, and therefore does not have much future potential.

## 20 Disclosure of Invention

The present invention aims to provide a recording medium which enables graphics to be moved smoothly like moving pictures.

The stated aim can be achieved by a recording medium  
25 used for storing data, including a digital stream generated by multiplexing a video stream and a graphics stream, wherein: the graphics stream is a sequence of a plurality of packets which include a packet containing control information; and

the control information indicates that graphics data contained in a preceding packet in the sequence is to be displayed at a predetermined time in a state of being overlaid on the video stream.

5           Control information indicates that a display is to be produced using graphics data that precedes the control information. Accordingly, a display position of graphics can be changed by feeding only control information showing new coordinates of the graphics into a reproduction apparatus.  
10   Equally, a color of graphics can be changed by feeding only appropriate control information into the reproduction apparatus.

          Since a graphics display can be updated using only control information, graphics is easily brought into  
15   synchronization with video.

          Usually, a picture pattern of graphics itself need not be varied in order to change a display position of the graphics. This is because the human eye cannot perceive a moving object so distinctly. This being so, the technique provided by the  
20   present invention is suitable for displaying the same graphics while changing its position at high speed.

#### Brief Description of Drawings

          FIG. 1 shows an example application of a recording medium  
25   to which embodiments of the present invention relate.

          FIG. 2 shows a structure of a BD-ROM shown in FIG. 1.

          FIG. 3 shows a structure of an AV Clip.

          FIG. 4A shows a structure of a Presentation graphics

stream.

FIG. 4B shows PES packets which contain functional Segments.

FIG. 5 shows a logical structure made up of various types  
5 of functional Segments.

FIG. 6 shows a relationship between subtitle display positions and Epochs.

FIG. 7A shows a data structure of an ODS.

FIG. 7B shows a data structure of a PDS.

10 FIG. 8A shows a data structure of a WDS.

FIG. 8B shows a data structure of a PCS.

FIG. 9 shows an example description of DSs for displaying subtitles.

FIG. 10 shows an example description of a PCS and a WDS  
15 in DS1.

FIG. 11 shows an example description of a PCS in DS2.

FIG. 12 shows an example description of a PCS in DS3.

FIG. 13 shows a memory space in an Object Buffer when performing graphics updates such as those shown in FIGS. 10  
20 to 12.

FIG. 14 shows an example algorithm of calculating a DECODEDURATION.

FIG. 15 is a flowchart of the algorithm shown in FIG.  
14.

25 FIGS. 16A and 16B are flowcharts of the algorithm shown in FIG. 14.

FIG. 17A shows a situation where one graphics Object exists in one Window.

FIGS. 17B and 17C are timing charts showing parameters used in the algorithm shown in FIG. 14.

FIG. 18A shows a situation where two graphics Objects exist in one Window.

5        FIGS. 18B and 18C are timing charts showing parameters used in the algorithm shown in FIG. 14.

FIG. 19A shows a situation where two graphics Objects exist respectively in two Windows.

10        FIG. 19B is a timing chart when decode period (2) is longer than a sum of clear period (1) and write period (31).

FIG. 19C is a timing chart when the sum of clear period (1) and write period (31) is longer than decode period (2).

FIG. 20 shows forward reference PCSs.

15        FIG. 21A shows an Epoch that produces a display effect of moving graphics on a screen.

FIG. 21B shows contents and PTSs of PCSs in DS1 to DS8.

FIG. 22A shows an ODS in DS0.

FIG. 22B shows positions of coordinates (x1,y1), (x2,y2), (x3,y3), ..., (x8,y8) in a coordinate system defined by a Window.

20        FIG. 23 shows a settings of a time stamp of a functional Segments in each DS.

FIG. 24 shows a specific example of successive graphics updates.

25        FIG. 25 shows a series of DSs for realizing a Palette-only Display Update.

FIG. 26A shows contents of PDSs in DS0.

FIG. 26B shows contents of PCSs in DS0 to DS3.

FIG. 27 shows a display effect achieved by feeding the

four DSs.

FIG. 28 shows an internal construction of a reproduction apparatus to which the embodiments of the present invention relate.

5        FIG. 29 shows transfer rates Rx, Rc, and Rd and sizes of a Graphics Plane, a Coded Data Buffer, and an Object Buffer shown in FIG. 28.

FIG. 30 is a timing chart of pipeline processing in the reproduction apparatus.

10        FIG. 31 is a timing chart of pipeline processing when decoding of ODSs ends before clearing of the Graphics Plane.

FIG. 32 is a timing chart showing changes in occupancy of the Composition Buffer, the Object Buffer, the Coded Data Buffer, and the Graphics Plane.

15        FIG. 33 is a flowchart of an operation of loading functional Segments.

FIG. 34 shows a case when a skip operation is performed.

FIG. 35 shows a situation where DS10 is loaded into the Coded Data Buffer when the skip operation is performed as  
20 shown in FIG. 34.

FIG. 36 shows a case when normal reproduction is performed.

FIG. 37 shows a situation where DS1 and DS20 are loaded into the Coded Data Buffer when the normal reproduction is  
25 performed as shown in FIG. 36.

FIG. 38 is a flowchart of an operation of a Graphics Controller shown in FIG. 28.

FIG. 39 is a flowchart of the operation of the Graphics

Controller.

FIG. 40 is a flowchart of the operation of the Graphics Controller.

FIG. 41 shows manufacturing steps of the BD-ROM.

### Best Mode for Carrying out the Invention

(First Embodiment)

The following is a description on a recording medium to which a first embodiment of the present invention relates.

10 First, use of the recording medium is explained below. FIG. 1 shows an example application of the recording medium. In the drawing, the recording medium is a BD-ROM 100. The BD-ROM 100 is used for providing a movie film in a home theater system that includes a reproduction apparatus 200, a television 300,  
15 and a remote control 400.

Production of the recording medium is explained next. The recording medium can be realized by making improvements to an application layer of a BD-ROM. FIG.2 shows an example structure of the BD-ROM 100.

20 In the drawing, the fourth level shows the BD-ROM 100, and the third level shows a track on the BD-ROM 100. The track is shown as being stretched out into a straight line, though in actuality the track spirals outwards from the center of the BD-ROM 100. The track includes a lead-in area, a volume area, and a lead-out area. The volume area has a layer model  
25 of a physical layer, a file system layer, and an application layer. The first level shows a format of the application layer (application format) of the BD-ROM 100 in a directory structure.

As illustrated, the BD-ROM 100 has a BDMV directory below a ROOT directory. The BDMV directory contains a file (XXX.M2TS) storing an AV Clip, a file (XXX.CLPI) storing management information of the AV Clip, and a file (YYY.MPLS) defining a logical playback path (playlist) for the AV Clip. The BD-ROM 100 can be realized by generating such an application format. If there are more than one file for each of the above file types, three directories named STREAM, CLIPINF, and PLAYLIST may be provided below the BDMV directory, to store files of the same type as XXX.M2TS, files of the same type as XXX.CLPI, and files of the same type as YYY.MPLS respectively.

The AV Clip (XXX.M2TS) in this application format is explained below.

The AV Clip (XXX.M2TS) is a digital stream of the MPEG-TS (Transport Stream) format, and is obtained by multiplexing a video stream, at least one audio stream, and a Presentation graphics stream. The video stream represents a moving picture of the film, the audio stream represents audio of the film, and the Presentation graphics stream represents subtitles of the film. FIG. 3 shows a structure of the AV Clip (XXX.M2TS).

In the drawing, the middle level shows the AV Clip. This AV Clip can be created as follows. The video stream made up of a plurality of video frames (pictures pj1, pj2, pj3, ...) and the audio stream made up of a plurality of audio frames on the upper first level are each converted to PES packets on the upper second level, and further converted to TS packets on the upper third level. Likewise, the Presentation graphics

stream on the lower first level is converted to PES packets on the lower second level, and further converted to TS packets on the lower third level. These TS packets of the video, audio, and Presentation graphics streams are multiplexed to form  
5 the AV Clip.

FIG. 3 shows an example where only one Presentation graphics stream is multiplexed in the AV Clip. If the BD-ROM 100 supports multiple languages, however, a Presentation graphics stream for each of the languages is multiplexed in  
10 the AV Clip. The AV Clip generated in the above manner is divided into a plurality of extents in the same way as computer files, and stored on the BD-ROM 100.

The following explains the Presentation graphics stream. FIG. 4A shows a structure of the Presentation graphics stream.  
15 In the drawing, the first level shows the TS packet string which constitutes the AV Clip. The second level shows the PES packet string which constitutes the Presentation graphics stream. This PES packet string is formed by connecting payloads of TS packets having a predetermined PID from the  
20 TS packet string on the first level.

The third level shows the structure of the Presentation graphics stream. The Presentation graphics stream is made up of functional Segments that include a PCS (Presentation Composition Segment), a WDS (Window Definition Segment), a  
25 PDS (Palette Definition Segment), an ODS (Object Definition Segment), and an END (End of Display Set Segment). Of these functional Segments, the PCS is a screen Composition Segment, whereas the WDS, the PDS, and the ODS are Definition Segments.

One functional Segment corresponds to either one PES packet or a plurality of PES packets. Which is to say, one functional Segment is converted to one PES packet and recorded on the BD-ROM 100, or split into fragments which are converted to  
5 PES packets and recorded on the BD-ROM 100.

FIG. 4B shows PES packets containing functional Segments. As illustrated, each PES packet is made up of a packet header and a payload. The payload carries a functional Segment, and the packet header carries a DTS and a PTS associated with  
10 the functional Segment. Hereafter, a DTS and a PTS in a packet header of a PES packet which contains a functional Segment are regarded as a DTS and a PTS of that functional Segment.

These various types of functional Segments form a logical structure such as the one shown in FIG. 5. In the drawing,  
15 the third level shows the functional Segments, the second level shows DSs (Display Sets), and the first level shows Epochs.

ADS on the second level is a group of functional Segments, in the Presentation graphics stream, which are used for  
20 creating one screen of graphics. Dashed lines hk2 show which DS the functional Segments on the third level belong to. As can be seen from the drawing, the series of functional Segments PCS-WDS-PDS-ODS-END composes one DS. The reproduction apparatus 200 reads these functional Segments which compose  
25 the DS from the BD-ROM 100, to produce one screen of graphics.

An Epoch on the first level refers to one time unit of continuous memory management on a reproduction time axis of the AV Clip, and to a group of data allocated to that time

unit. Memory mentioned here includes a Graphics Plane for storing one screen of graphics and an Object Buffer for storing uncompressed graphics data. Continuous memory management means that throughout the Epoch neither the Graphics Plane  
5 nor the Object Buffer is flushed and deletion and rendering of graphics are performed only within a predetermined rectangular area of the Graphics Plane (to flush means to clear the entire Graphics Plane or the entire Object Buffer). A size and a position of this rectangular area are fixed during  
10 the Epoch. So long as deletion and rendering of graphics are performed within this fixed rectangular area of the Graphics Plane, synchronization of video and graphics is guaranteed. In other words, the Epoch is a time unit, on the reproduction time axis of the AV Clip, during which synchronization of  
15 video and graphics can be guaranteed. To change the graphics deletion/rendering area in the Graphics Plane, it is necessary to define a point of change on the reproduction time axis and set a new Epoch from the point onward. Synchronization of video and graphics is not guaranteed in a boundary between  
20 the two Epochs.

In regard to subtitling, the Epoch is a time period, on the reproduction time axis, during which subtitles appear within the fixed rectangular area on a screen. FIG. 6 shows a relationship between subtitle display positions and Epochs.  
25 In the drawing, subtitle display positions are changed depending on patterns of pictures. In more detail, three subtitles "Actually", "I lied to you.", and "Sorry." are positioned at the bottom of the screen, whereas two subtitles

"Three years have passed" and "since then." are positioned at the top of the screen. Thus, the subtitle display positions are changed from one margin to another on the screen, to enhance visibility. In such a case, on the reproduction time axis of the AV Clip, a time period during which the subtitles are displayed at the bottom of the screen is Epoch1, and a time period during which the subtitles are displayed at the top of the screen is Epoch2. These two Epochs each have an individual subtitle rendering area. In Epoch1, the subtitle rendering area is Window1 that corresponds to the bottom margin of the screen. In Epoch2, the subtitle rendering area is Window2 that corresponds to the top margin of the screen. In each of Epoch1 and Epoch2, memory management of the Object Buffer and the Graphics Plane is continuous, so that the subtitles are displayed seamlessly in the corresponding margin of the screen. This completes the explanation on an Epoch.

The following explains a DS.

In FIG. 5, dashed lines hk1 indicate which Epoch DSs on the second level belong to. As illustrated, a series of DSs that are an Epoch Start DS, an Acquisition Point DS, and a Normal Case DS constitutes one Epoch on the first level. Here, Epoch Start, Acquisition Point, and Normal Case are types of DSs. Though the Acquisition Point DS precedes the Normal Case DS in FIG. 5, they may be arranged in reverse order.

The Epoch Start DS provides a display effect "new display", and indicates a start of a new Epoch. The Epoch

Start DS contains all functional Segments necessary for the next screen composition. The Epoch Start DS is provided in a position which is to be a destination of a skip operation, such as a start of a chapter in a film.

5       The Acquisition Point DS provides a display effect "display refresh", and is identical to the preceding Epoch Start DS. The Acquisition Point DS is not the start of the Epoch, but contains all functional Segments necessary for the next screen composition. Therefore, graphics can be  
10   displayed reliably when reproduction is started from the Acquisition Point DS. Which is to say, the Acquisition Point DS enables a screen composition to be made from a midpoint in the Epoch.

      The Acquisition Point DS is provided in a position which  
15   can be a destination of a skip operation, such as a position that may be designated by a time search. The time search is an operation of locating a reproduction point corresponding to a time input by a user in minutes/seconds. The time input is made in a relatively large unit such as ten minutes or  
20   ten seconds. Accordingly, the Acquisition Point DS is provided in a position that can be designated by a time search made in units of ten minutes or ten seconds. By providing the Acquisition Point DS in a position that can be designated  
by a time search, the graphics stream can be smoothly reproduced  
25   when a time search is conducted.

      The Normal Case DS provides a display effect "display update", and contains only a difference from the previous screen composition. For example, if DSv has the same subtitle

as immediately preceding DSu but a different screen composition from DSu, DSv is a Normal Case DS which contains only a PCS and an END. This makes it unnecessary to provide overlapping ODSs in DSs, with it being possible to reduce the amount of data stored on the BD-ROM 100. Since the Normal Case DS contains only the difference, graphics cannot be displayed with the Normal Case DS alone.

The following explains the ODS, the WDS, and the PDS (Definition Segments).

The ODS is a functional Segment for defining a graphics Object. AV Clips recorded on BD-ROMs feature an image quality as high as high-definition television. This being so, graphics Objects are set at a high resolution of 1920×1080 pixels. This high resolution allows theater screen-style subtitles, i.e. elegant handwriting-style subtitles, to be reproduced vividly on BD-ROMs. A graphics Object is made up of a plurality of pieces of run-length data. Run-length data expresses a pixel string using a Pixel Code which shows a pixel value and a continuous length of the pixel value. The Pixel Code has 8 bits, and shows one of the values from 1 to 255. Through the use of this Pixel Code, the run-length data sets arbitrary 256 pixel colors out of full color (16,777,216 colors). Note that it is necessary to place a character string on a background of a transparent color in order to display a graphics Object as a subtitle.

The ODS defines a graphics Object according to a data structure shown in FIG. 7A. As shown in the drawing, the ODS includes a segment\_type field showing a Segment type "ODS",

a segment\_length field showing a data length of the ODS, an object\_id field identifying the graphics Object in the Epoch, an object\_version\_number field showing a version of the ODS in the Epoch, a last\_in\_sequence\_flag field, and an  
5 object\_data\_fragment field carrying a consecutive sequence of bytes corresponding to part or all of the graphics Object.

In more detail, the object\_id field shows an identifier which identifies the graphics Object and a storage area in the Object Buffer that is occupied by the graphics Object,  
10 when the ODS is decoded and the graphics Object is buffered in the Object Buffer. This being so, when one or more graphics Objects are present in the Object Buffer, each individual storage area in the Object Buffer is identified by an object\_id field value. Suppose one object\_id is assigned to two or more  
15 ODSs. In such a case, after a graphics Object corresponding to one ODS is stored in the Object Buffer, that graphics Object is overwritten by a graphics Object corresponding to a succeeding ODS with the same object\_id. Such an update intends to prevent occurrence of many small free spaces in the Object  
20 Buffer and scattering of graphics Objects in the Object Buffer. When displaying graphics, graphics Objects in the Object Buffer are constantly transferred to the Graphics Plane. This being so, if many small free spaces exist in the Object Buffer or one graphics Object is scattered in the Object Buffer,  
25 overhead for reading graphics Objects causes a reduction in efficiency of transfer from the Object Buffer to the Graphics Plane. Such a reduction in transfer efficiency may affect synchronous display of graphics and video. To prevent this,

an existing graphics Object in the Object Buffer is overwritten by a new graphics Object having the same object\_id.

Here, the new graphics Object overwriting the existing graphics Object needs to be equal in size to the existing graphics Object, that is, the new graphics Object can be neither smaller nor larger than the existing graphics Object. At the time of authoring, therefore, an author needs to make these graphics Objects equal in size. This size constraint that graphics Objects having the same object\_id need be equal in width and height applies only within an Epoch. Graphics Objects having the same object\_id need not be equal in size if they belong to different Epochs.

The last\_in\_sequence\_flag field and the object\_data\_fragment field are explained next. Due to a constraint of payloads of PES packets, uncompressed graphics constituting one subtitle may not be able to be contained in one ODS. In such a case, the graphics is split into a plurality of fragments and one of such fragments is carried in the object\_data\_fragment field. When storing one graphics Object across a plurality of ODSs, every fragment except the last fragment is of the same size. That is, the last fragment is less than or equal to the size of the preceding fragments. The ODSs carrying these fragments of the graphics Object appear in the DS in sequence. The last\_in\_sequence\_flag field indicates an end of the graphics Object. Though the above ODS data structure is based on a method of storing fragments in consecutive PES packets without a gap, the fragments may instead be stored in PES packets so as to leave some gaps

in the PES packets.

The PDS is a functional Segment for defining a Palette used for color conversion. The Palette is data showing combinations of Pixel Codes of 1 to 255 and pixel values.

5 A pixel value referred to here is made up of a red color difference component (Cr value), a blue color difference component (Cb value), a luminance component (Y value), and a transparency (T value). Substituting a Pixel Code of each piece of run-length data into a pixel value on the Palette

10 produces a color. FIG. 7B shows a data structure of the PDS. As shown in the drawing, the PDS includes a segment\_type field showing a Segment type "PDS", a segment\_length field showing a data length of the PDS, a palette\_id field uniquely identifying the Palette, a palette\_version\_number field

15 showing a version of the PDS within the Epoch, and a palette\_entry field carrying information for each entry. The palette\_entry field shows a red color difference component (Cr\_value), a blue color difference component (Cb\_value), a luminance component (Y\_value), and a transparency (T\_value)

20 for each entry.

The WDS is a functional Segment for defining a rectangular area on the Graphics Plane. As mentioned earlier, memory management is continuous within an Epoch during which clearing and rendering are performed in a fixed rectangular

25 area on the Graphics Plane. This rectangular area on the Graphics Plane is called a Window, which is defined by the WDS. FIG. 8A shows a data structure of the WDS. As shown in the drawing, the WDS includes a window\_id field uniquely

identifying the Window on the Graphics Plane, a  
window\_horizontal\_position field specifying a horizontal  
position of a top left pixel of the Window on the Graphics  
Plane, a window\_vertical\_position field specifying a vertical  
5 position of the top left pixel of the Window on the Graphics  
Plane, a window\_width field specifying a width of the Window  
on the Graphics Plane, and a window\_height field specifying  
a height of the Window on the Graphics Plane.

The window\_horizontal\_position field, the  
10 window\_vertical\_position field, the window\_width field, and  
the window\_height field can take the following values. The  
Graphics Plane serves as a coordinate system for these field  
values. This Graphics Plane has a two-dimensional size  
defined by video\_height and video\_width parameters.

15 The window\_horizontal\_position field specifies the  
horizontal position of the top left pixel of the Window on  
the Graphics Plane, and accordingly takes a value in a range  
of 0 to (video\_width)-1. The window\_vertical\_position field  
specifies the vertical position of the top left pixel of the  
20 Window on the Graphics Plane, and accordingly takes a value  
in a range of 0 to (video\_height)-1.

The window\_width field specifies the width of the Window  
on the Graphics Plane, and accordingly takes a value in a  
range of 1 to (video\_width)-(window\_horizontal\_position).  
25 The window\_height field specifies the height of the Window  
on the Graphics Plane, and accordingly takes a value in a  
range of 1 to (video\_height)-(window\_vertical\_position).

A position and size of a Window can be defined for each

Epoch, using these window\_horizontal\_position,  
window\_vertical\_position, window\_width, and window\_height  
fields in the WDS. This makes it possible for the author to  
adjust, at the time of authoring, a Window to appear in a  
5 desired margin of each picture in an Epoch so as not to interfere  
with a pattern of the picture. Graphics for subtitles  
displayed in this way can be viewed clearly. The WDS can be  
defined for each Epoch. Accordingly, when the pattern of the  
picture changes with time, graphics can be moved based on  
10 such a change so as not to decrease visibility. This enhances  
the quality of the film to the same level as in the case where  
subtitles are integrated in a moving picture.

The following explains the END. The END is a functional  
Segment indicating that the transmission of the DS is complete.  
15 The END is positioned immediately after the last ODS in the  
DS. The END includes a segment\_type field showing a Segment  
type "END" and a segment\_length field showing a data length  
of the END. These fields are not main features of the present  
invention and therefore their explanation has been omitted.

20 The following explains the PCS (Composition Segment).

The PCS is a functional Segment for composing a screen  
that can be synchronized with a moving picture. FIG. 8B shows  
a data structure of the PCS. As shown in the drawing, the  
PCS includes a segment\_type field, a segment\_length field,  
25 a composition\_number field, a composition\_state field, a  
palette\_update\_flag field, a palette\_id\_ref field, and  
composition\_object(1) to composition\_object(m) fields.

The composition\_number field uniquely identifies a

graphics update in the DS, using a number from 0 to 15. In more detail, the `composition_number` field is incremented by 1 for each graphics update from the beginning of the Epoch to the PCS.

5       The `composition_state` field indicates whether the DS is a Normal Case DS, an Acquisition Point DS, or an Epoch Start DS.

      The `palette_update_flag` field shows whether the PCS describes a Palette-only Display Update. The Palette-only  
10 Display Update refers to such an update that only replaces a previous Palette with a new Palette. To indicate a Palette-only Display Update, the `palette_update_flag` field is set to 1.

      The `palette_id_ref` field specifies the Palette to be  
15 used in the DS.

      The `composition_object(1)` to `composition_object(m)` fields each contain control information for realizing a screen composition in the DS. In FIG. 8B, dashed lines wdl indicate an internal structure of `composition_object(i)` as one example.  
20 As illustrated, `composition_object(i)` includes an `object_id_ref` field, a `window_id_ref` field, an `object_cropped_flag` field, an `object_horizontal_position` field, an `object_vertical_position` field, and `cropping_rectangle` information(1) to `cropping_rectangle`  
25 information(n).

      The `object_id_ref` field shows a reference value of an identifier of a graphics Object (`object_id`). This reference value specifies the graphics Object that is to be used in

order to produce a screen composition corresponding to composition\_object(i).

The window\_id\_ref field shows a reference value of an identifier of a Window (window\_id). This reference value  
5 specifies the Window in which the graphics Object is to be displayed in order to produce the screen composition corresponding to composition\_object(i).

The object\_cropped\_flag field shows whether the graphics Object cropped in the Object Buffer is to be displayed  
10 or not. When the object\_cropped\_flag field is set to 1, the graphics Object cropped in the Object Buffer is displayed. When the object\_cropped\_flag field is set to 0, the graphics Object cropped in the Object Buffer is not displayed.

The object\_horizontal\_position field specifies a  
15 horizontal position of a top left pixel of the graphics Object on the Graphics Plane.

The object\_vertical\_position field specifies a vertical position of the top left pixel of the graphics Object on the Graphics Plane.

20 The cropping\_rectangle information(1) to cropping\_rectangle information(n) fields are valid when the object\_cropped\_flag field value is 1. Dashed lines wd2 indicate an internal structure of cropping\_rectangle information(i) as one example. As illustrated,  
25 cropping\_rectangle information(i) includes an object\_cropping\_horizontal\_position field, an object\_cropping\_vertical\_position field, an object\_cropping\_width field, and an object\_cropping\_height

field.

The `object_cropping_horizontal_position` field specifies a horizontal position of a top left corner of a cropping rectangle in the graphics Object. The cropping  
5 rectangle is used for taking out one part of the graphics Object, and corresponds to a "region" in ETSI EN 300 743.

The `object_cropping_vertical_position` field specifies a vertical position of the top left corner of the cropping rectangle in the graphics Object.

10 The `object_cropping_width` field specifies a horizontal length of the cropping rectangle in the graphics Object.

The `object_cropping_height` field specifies a vertical length of the cropping rectangle in the graphics Object.

The following explains a specific description of the  
15 PCS, using an example where the three subtitles "Actually", "I lied to you.", and "Sorry." shown in FIG. 6 are displayed sequentially by three operations of writing to the Graphics Plane as the reproduction of the moving picture progresses. FIG. 9 shows an example description for realizing such  
20 subtitling. In the drawing, an Epoch has DS1 (Epoch Start DS), DS2 (Normal Case DS), and DS3 (Normal Case DS). DS1 includes a WDS defining a Window in which the subtitles are to be displayed, an ODS showing the line "Actually I lied to you. Sorry.", and a PCS. DS2 includes a PCS. DS3 includes  
25 a PCS.

Each of these PCSs has the following description. FIGS. 10 to 12 show example descriptions of the WDS and the PCSs belonging to DS1 to DS3.

FIG. 10 shows descriptions of the PCS and the WDS in DS1. In the drawing, a window\_horizontal\_position field value and a window\_vertical\_position field value in the WDS specify top left coordinates LP1 of the Window on the Graphics Plane, and a window\_width field value and a window\_height field value in the WDS specify a width and height of the Window.

An object\_cropping\_horizontal\_position field value and an object\_cropping\_vertical\_position field value of cropping\_rectangle information in the PCS specify top left coordinates ST1 of a cropping rectangle in a coordinate system whose origin is top left coordinates of the graphics Object in the Object Buffer. The cropping rectangle is an area (enclosed by a thick-line box) defined by an object\_cropping\_width field value and an

object\_cropping\_height field value from top left coordinates ST1. A cropped graphics Object is positioned in area cpl (enclosed by a dashed-line box) so that a top left corner of the cropped graphics Object lies at a pixel specified by an object\_horizontal\_position field value and an

object\_vertical\_position field value in the coordinate system of the Graphics Plane. In this way, the subtitle "Actually" out of "Actually I lied to you. Sorry." is written into the Window on the Graphics Plane. The subtitle "Actually" is overlaid on a picture and a resultant image is displayed.

FIG. 11 shows a description of the PCS in DS2. Since the description of the WDS in the drawing is the same as that in FIG. 10, its explanation has been omitted. Meanwhile, the description of cropping\_rectangle information differs from

that in FIG. 10. In FIG. 11, an  
object\_cropping\_horizontal\_position field value and an  
object\_cropping\_vertical\_position field value in  
cropping\_rectangle information specify top left coordinates  
5 of a cropping rectangle corresponding to the subtitle "I lied  
to you." in the Object Buffer, and an object\_cropping\_height  
field value and an object\_cropping\_width field value specify  
a height and width of the cropping rectangle. As a result,  
the subtitle "I lied to you." is written into the Window on  
10 the Graphics Plane. The subtitle "I lied to you." is overlaid  
on a picture and a resultant image is displayed.

FIG. 12 shows a description of the PCS in DS3. Since  
the description of the WDS in the drawing is the same as that  
in FIG. 10, its explanation has been omitted. Meanwhile, the  
15 description of cropping\_rectangle information differs from  
that in FIG. 10. In FIG. 12, an  
object\_cropping\_horizontal\_position field value and an  
object\_cropping\_vertical\_position field value specify top  
left coordinates of a cropping rectangle corresponding to  
20 the subtitle "Sorry." in the Object Buffer, and an  
object\_cropping\_height field value and an  
object\_cropping\_width field value specify a height and width  
of the cropping rectangle. As a result, the subtitle "Sorry."  
is written into the Window on the Graphics Plane. The subtitle  
25 "Sorry." is overlaid on a picture and a resultant image is  
displayed. FIG. 13 shows a memory space of the Object Buffer  
when performing graphics updates such as those shown in FIG.  
10 to 12. As illustrated, the Object Buffer has four storage

areas A to D which each have a fixed height and width and a fixed position. Of storage areas A to D, the subtitle shown in FIG. 10 is stored in storage area A. Each of storage areas A to D is identified by an object\_id corresponding to a graphics Object to be stored in that storage area. In detail, storage area A is identified by object\_id=1, storage area B is identified by object\_id=2, storage area C is identified by object\_id=3, and storage area D is identified by object\_id=4. To maintain an efficiency of transfer from the Object Buffer to the Graphics Plane, the height and width of each of storage areas A to D are fixed. This being so, when a graphics Object having some object\_id is obtained as a result of decoding, that graphics Object is written in a storage area identified by the object\_id over an existing graphics Object. For example, to display a subtitle in the same position and size as the subtitles displayed in FIGS. 10 to 12, an ODS having the same object\_id as the ODS in DS1 needs to be provided in a succeeding DS. By adding the same object\_id in such a way, a graphics Object in the Object Buffer is overwritten by a new graphics Object, which is displayed in the same position and size as the overwritten graphics Object.

The following explains constraints for achieving display effects. To display subtitles smoothly, it is necessary to perform clearing and rendering on a Window. When performing Window clearing and Window rendering at a frame rate of video frames, the following rate of transfer from the Object Buffer to the Graphics Plane is required.

First, a constraint on the size of the Window is examined.

Let  $R_c$  be the transfer rate from the Object Buffer to the Graphics Plane. In a worst-case scenario, the Window clearing and the Window rendering need to be performed at  $R_c$ . In other words, each of the Window clearing and the Window rendering  
5 needs to be performed at half of  $R_c$  ( $R_c/2$ ).

To synchronize the Window clearing and the Window rendering with a video frame,

$$(\text{Window size}) \times (\text{frame rate}) \approx R_c/2$$

10

needs to be satisfied. If the frame rate is 29.97,

$$R_c = (\text{Window size}) \times 2 \times 29.97$$

15

To display a subtitle, the size of the Window needs to be at least about 25% to 33% of the entire Graphics Plane. If a total number of pixels of the Graphics Plane is  $1920 \times 1080$  and a bit length of an index per pixel is 8 bits, a total capacity of the Graphics Plane is 2 Mbytes ( $\approx 1920 \times 1080 \times 8$ ).

20

Suppose the size of the Window is  $1/4$  of the Graphics Plane, i.e., 500 Kbytes ( $= 2 \text{ Mbytes} / 4$ ). Substituting this to the above formula yields  $R_c = 256 \text{ Mbps}$  ( $500 \text{ Kbytes} \times 2 \times 29.97$ ).

25

Thus, if the size of the Window is about 25% to 33% of the Graphics Plane, display effects of subtitles can be achieved without losing synchronization with a moving picture, so long as the subtitles are displayed with  $R_c = 256 \text{ Mbps}$ .

If the Window clearing and the Window rendering may be performed at  $1/2$  or  $1/4$  of the video frame rate, the size

of the Window can be doubled or quadrupled with the same  $R_c$ . The following explains a position and range of a Window. As mentioned earlier, a position and range of a Window are fixed within an Epoch, for the following reason.

5           If the position or range of the Window varies in the Epoch, a write address to the Graphics Plane needs to be changed. This incurs overhead, which causes a drop in transfer rate  $R_c$  from the Object Buffer to the Graphics Plane.

10           A number of graphics Objects that can be displayed simultaneously in one Window is limited, in order to reduce overhead when transferring decoded graphics Objects to the Graphics Plane. The overhead mentioned here occurs when setting addresses of edge parts of the graphics Objects. This overhead increases if the number of edge parts is greater.

15           If there is no limitation on the number of graphics Objects that can be displayed in one Window, the overhead occurs unlimitedly when transferring graphics objects to the Graphics Plane, which increases a variation in transfer load. On the other hand, if the number of graphics Objects in one  
20 Window is limited to 2, transfer rate  $R_c$  can be set on an assumption that the number of instances of overhead is 4 at the worst. Hence a minimum standard for transfer rate  $R_c$  can be determined easily. This completes the explanation on a Window.

25           The following explains how DSSs carrying functional Segments such as PCSs and ODSs described above are allocated on the reproduction time axis of the AV Clip. An Epoch is a time period on the reproduction time axis during which memory

management is continuous, and is made up of one or more DSs. Hence it is important to effectively allocate DSs on the reproduction time axis of the AV Clip. The reproduction time axis of the AV Clip mentioned here is a time axis for defining  
5 decoding times and presentation times of individual pictures which constitute the video stream multiplexed in the AV Clip. Decoding times and presentation times on the reproduction time axis are expressed with a time accuracy of 90KHz. DTSS and PTSS of PCSs and ODSs in DSs specify timings for synchronous  
10 control on this reproduction time axis. In other words, the DSs are allocated on the reproduction time axis by exercising synchronous control using the DTSS and PTSS of the PCSs and ODSs.

Synchronous control exercised using a DTS and a PTS of  
15 an ODS is explained first.

The DTS shows a time at which a decoding process of the ODS is to be started, with an accuracy of 90KHz. The PTS shows a time at which the decoding process of the ODS is to be completed, with an accuracy of 90KHz.

20 The decoding process is made up of decoding the ODS and transferring an uncompressed graphics Object generated by the decoding to the Object Buffer. This decoding process does not complete instantaneously, but requires a certain length of time. The DTS and the PTS of the ODS respectively show  
25 the decoding start time and the decoding end time of the ODS, to specify the beginning and end of the decoding process.

Since the time shown by the PTS is a deadline, it is necessary to decode the ODS and store an uncompressed graphics

Object in the Object Buffer by the time shown by the PTS.

A decoding start time of arbitrary ODSj in DS<sub>n</sub> is specified by DTS(DS<sub>n</sub>[ODSj]) with an accuracy of 90KHz. This being so, a decoding end time of ODSj in DS<sub>n</sub> (i.e.

5 PTS(DS<sub>n</sub>[ODSj]) is a sum of DTS(DS<sub>n</sub>[ODSj]) and a maximum time required for a decoding process.

Let SIZE(DS<sub>n</sub>[ODSj]) denote a size of ODSj, and Rd denote an ODS decoding rate. Then the maximum time required for the decoding process (in seconds) is SIZE(DS<sub>n</sub>[ODSj])/Rd. The  
10 symbol "//" represents an operator for a division with a fractional part being rounded up.

By converting this maximum time to the accuracy of 90KHz and adding the result to the DTS of ODSj, the decoding end time of ODSj specified by the PTS is calculated with the  
15 accuracy of 90KHz.

This PTS of ODSj in DS<sub>n</sub> can be expressed by the following formula:

$$\begin{aligned} \text{PTS}(\text{DS}_n[\text{ODS}_j]) &= \text{DTS}(\text{DS}_n[\text{ODS}_j]) + 90,000 \\ &\times (\text{SIZE}(\text{DS}_n[\text{ODS}_j]) // \text{Rd}) \end{aligned}$$

20

Also, two adjacent ODSs (ODSj and ODSj+1) in DS<sub>n</sub> need to satisfy the following relationship:

$$\text{PTS}(\text{DS}_n[\text{ODS}_j]) \leq \text{DTS}(\text{DS}_n[\text{ODS}_{j+1}])$$

25

An END in DS<sub>n</sub> indicates an end of DS<sub>n</sub>. Therefore, the END shows a decoding end time of a last ODS (ODS<sub>last</sub>) in DS<sub>n</sub>.

The decoding end time of ODSlast is shown by a PTS of ODSlast (PTS(DSn[ODSlast])), so that a PTS of the END is set as follows:

$$\text{PTS}(\text{DSn}[\text{END}]) = \text{PTS}(\text{DSn}[\text{ODSlast}])$$

5

Meanwhile, a DTS and a PTS of a PCS in DSn are set in the following manner.

The DTS of the PCS shows either a decoding start time of a top ODS (ODS1) in DSn or a time earlier than that. This is because the PCS needs to be loaded in a buffer of the reproduction apparatus 200 at the same time as or earlier than the decoding start time of ODS1 (DTS(DSn[ODS1])) and a time at which a top PDS (PDS1) in DSn becomes valid (PTS(DSn[PDS1])). Which is to say, the DTS of the PCS needs to satisfy the following formulas:

$$\text{DTS}(\text{DSn}[\text{PCS}]) \leq \text{DTS}(\text{DSn}[\text{ODS1}])$$

$$\text{DTS}(\text{DSn}[\text{PCS}]) \leq \text{PTS}(\text{DSn}[\text{PDS1}])$$

20 On the other hand, the PTS of the PCS is calculated as follows:

$$\text{PTS}(\text{DSn}[\text{PCS}]) \geq \text{DTS}(\text{DSn}[\text{PCS}])$$

$$+ \text{DECODEDURATION}(\text{DSn})$$

25

Here, DECODEDURATION(DSn) indicates a time required for decoding and presenting all graphics Objects used for updates described in the PCS in DSn. Though DECODEDURATION(DSn) is

not a fixed value, it will not be affected by factors such as differences in state or implementation of reproduction apparatuses. When a graphics Object used for a screen composition described by the PCS in DS<sub>n</sub> is denoted by  
5 DS<sub>n</sub>.PCS.OBJ[j], DECODEDURATION(DS<sub>n</sub>) is varied by (i) a time required for Window clearing, (ii) a time required for decoding DS<sub>n</sub>.PCS.OBJ[j], and (iii) a time required for writing DS<sub>n</sub>.PCS.OBJ[j] on the Graphics Plane. Accordingly, DECODEDURATION(DS<sub>n</sub>) is the same regardless of implementations  
10 of reproduction apparatuses, so long as Rd and Rc are predetermined. Therefore, the length of each of the above time periods is calculated to specify the PTS of the PCS, at the time of authoring.

The calculation of DECODEDURATION(DS<sub>n</sub>) is carried out  
15 based on a program shown in FIG. 14. FIG. 15 and FIGS. 16A and 16B are flowcharts showing an algorithm of this program. A procedure of calculating DECODEDURATION(DS<sub>n</sub>) is explained below, with reference to these drawings. In FIG. 15, a PLANEINITIALIZATIONTIME function is called, and a return  
20 value is added to decode\_duration (S1). The PLANEINITIALIZATIONTIME function (FIG. 16A) is a function for calculating a time required for initializing the Graphics Plane in order to produce display for DS<sub>n</sub>. In step S1, this PLANEINITIALIZATIONTIME function is called using DS<sub>n</sub>,  
25 DS<sub>n</sub>.PCS.OBJ[0], and decode\_duration as arguments.

FIG. 16A shows a procedure of the PLANEINITIALIZATIONTIME function. In the drawing, initialize\_duration is a variable indicating a return value

of the PLANEINITIALIZATIONTIME function.

Step S2 judges whether a composition\_state field of the PCS in DSn shows Epoch Start. If the composition\_state field shows Epoch Start (S2:YES,

5 DSn.PCS.composition\_state==EPOCH\_START in FIG. 14), a time required for clearing the Graphics Plane is set as initialize\_duration (S3).

Suppose transfer rate Rc from the Object Buffer to the Graphics Plane is 256,000,000 and a total size of the Graphics  
10 Plane is (video\_width)\*(video\_height), as mentioned above. Then the time required for clearing the Graphics Plane (in seconds) is (video\_width)\*(video\_height)//256,000,000. This is multiplied by 90,000Hz, to express in the PTS accuracy. Hence the time required for clearing the Graphics Plane is  
15  $90,000 \times (\text{video\_width}) \times (\text{video\_height}) // 256,000,000$ . This is added to initialize\_duration, which is returned as a return value.

If the composition\_state field does not show Epoch Start (S2:NO), an operation of adding a time required for clearing  
20 Window[i] to initialize\_duration is carried out for all Windows[i] (S4). Suppose transfer rate Rc from the Object Buffer to the Graphics Plane is 256,000,000 as mentioned earlier, and a total size of Windows[i] is  $\sum \text{SIZE}(\text{WDS.WIN}[i])$ . Then a time required for clearing all Windows[i] (in seconds)  
25 is  $\sum \text{SIZE}(\text{WDS.WIN}[i]) // 256,000,000$ . This is multiplied by 90,000Hz to express in the PTS accuracy. Hence the time required for clearing all Windows[i] is  
 $90,000 \times \sum \text{SIZE}(\text{WDS.WIN}[i]) // 256,000,000$ . This is added to

initialize\_duration, which is returned as a return value.  
This completes the PLANEINITIALIZATIONTIME function.

Referring back to FIG. 15, step S5 judges whether a number of graphics Objects in DS<sub>n</sub> is 1 or 2

5 (if(DS<sub>n</sub>.PCS.num\_of\_objects==2,  
if(DS<sub>n</sub>.PCS.num\_of\_objects==1 in FIG. 14). If the number of graphics Objects in DS<sub>n</sub> is 1 (S5:=1), a wait time for decoding that graphics Object to complete is added to decode\_duration (S6). The wait time is calculated by calling a WAIT function  
10 (decode\_duration+=WAIT(DS<sub>n</sub>, DS<sub>n</sub>.PCS.OBJ[0],  
decode\_duration) in FIG. 14). The WAIT function is called using DS<sub>n</sub>, DS<sub>n</sub>.PCS.OBJ[0], and decode\_duration as arguments, and wait\_duration showing the wait time is returned as a return value.

15 FIG. 16B shows a procedure of the WAIT function.

In the WAIT function, current\_duration is a variable to which decode\_duration is set, and  
object\_definition\_ready\_time is a variable indicating a PTS of graphics Object OBJ[i] in DS<sub>n</sub>.

20 Also, current\_time is a variable indicating a sum of current\_duration and a DTS of the PCS in DS<sub>n</sub>. If  
object\_definition\_ready\_time is greater than current\_time (S7:YES, if(current\_time<object\_definition\_ready\_time) in FIG. 14), a difference between object\_definition\_ready\_time  
25 and current\_time is set to wait\_duration, which is returned as a return value (S8, wait\_duration +=  
object\_definition\_ready\_time - current\_time in FIG. 14).  
This completes the WAIT function.

Referring back to FIG. 15, a sum of the return value of the WAIT function and a time required for rendering on a Window to which OBJ[0] belongs

(90,000\*(SIZE(DSn.WDS.WIN[0]))//256,000,000) is set to  
5 decode\_duration (S9).

The above procedure relates to the case when the number of graphics Objects in DSn is 1. If the number of graphics Objects is 2 (S5:=2, if(DSn.PCS.num\_of\_objects==2) in FIG. 14), the WAIT function is called using DSn, DSn.PCS.OBJ[0],  
10 and decode\_duration as arguments, and a return value of the WAIT function is added to decode\_duration (S10).

Step S11 judges whether the Window to which OBJ[0] belongs is the same as a Window to which OBJ[1] belongs (if(DSn.PCS.OBJ[0].window\_id == DSn.PCS.OBJ[1].window\_id)  
15 in FIG. 14). If the judgement is in the affirmative (S11:YES), the WAIT function is called using DSn, DSn.PCS.OBJ[1], and decode\_duration as arguments, and a return value of the WAIT function is added to decode\_duration (S12). Furthermore, a time required for rendering on the Window to which OBJ[0]  
20 and OBJ[1] belong (90,000\*(SIZE(DSn.WDS.OBJ[0].window\_id)//256,000,000) is added to decode\_duration (S13).

If the judgement is in the negative (S11:NO), on the other hand, the time required for rendering on the Window  
25 to which OBJ[0] belongs (90,000\*(SIZE(DSn.WDS.OBJ[0].window\_id)//256,000,000) is added to decode\_duration (S15). After this, the WAIT function is called using DSn, DSn.PCS.OBJ[1], and decode\_duration as

arguments, and a return value of the WAIT function is added to decode\_duration (S16). Furthermore, a time required for rendering on the Window to which OBJ[1] belongs  $(90,000 \times (\text{SIZE}(\text{DSn.WDS.OBJ}[1].\text{window\_id}) // 256,000,000))$  is added to decode\_duration (S17). In this way, DECODEDURATION(DSn) is calculated.

The following explains how a PTS of a PCS in one DS is set, using specific examples.

FIG. 17A shows a situation where one OBJ (OBJ1) corresponding to one ODS (ODS1) belongs to one Window. FIGS. 17B and 17C are timing charts showing a relationship between parameters used in FIG. 14. Each of these timing charts has three levels. Of the three levels, the "Graphics Plane access" level and the "ODS decode" level indicate two processes which are performed in parallel when reproducing the ODS. The above algorithm is based on an assumption that these two processes are performed in parallel.

Graphics Plane access is made up of clear period (1) and write period (3). Clear period (1) indicates either a time required for clearing the entire Graphics Plane  $(90,000 \times ((\text{size of the Graphics Plane}) // 256,000,000))$  or a time required for clearing all Windows on the Graphics Plane  $(\sum (90,000 \times ((\text{size of Window}[i]) // 256,000,000)))$ .

Write period (3) indicates a time required for rendering on the entire Window  $(90,000 \times ((\text{size of the Window}) // 256,000,000))$ .

ODS decode is made up of decode period (2). Decode period (2) indicates a time period from a DTS to a PTS of ODS1.

Clear period (1), decode period (2), and write period (3) can vary depending on the range to be cleared, the size of an ODS to be decoded, and the size of a graphics Object to be written to the Graphics Plane. In FIG. 17, the beginning  
5 of decode period (2) is assumed to be the same as the beginning of clear period (1), for simplicity's sake.

FIG. 17B shows a case where decode period (2) is longer than clear period (1). In this case, `decode_duration` is a sum of decode period (2) and write period (3).

10 FIG. 17C shows a case where clear period (1) is longer than decode period (2). In this case, `decode_duration` is a sum of clear period (1) and write period (3).

FIGS. 18A to 18C show a situation where two OBJs (OBJ1 and OBJ2) corresponding to two ODSs (ODS1 and ODS2) belong  
15 to one Window. In FIGS. 18B and 18C, decode period (2) indicates a total time required for decoding ODS1 and ODS2. Likewise, write period (3) indicates a total time required for writing OBJ1 and OBJ2 to the Graphics Plane. Though the number of ODSs is two, `decode_duration` can be calculated in  
20 the same way as in FIG. 17. In detail, if decode period (2) of ODS1 and ODS2 is longer than clear period (1), `decode_duration` is a sum of decode period (2) and write period (3) as shown in FIG. 18B.

If clear period (1) is longer than decode period (2),  
25 `decode_duration` is a sum of clear period (1) and write period (3) as shown in FIG. 18C.

FIGS. 19A to 19C show a situation where OBJ1 belongs to Window1 and OBJ2 belongs to Window2. In this case too,

if clear period (1) is longer than decode period (2) of ODS1 and ODS2, decode\_duration is a sum of clear period (1) and write period (3). If clear period (1) is shorter than decode period (2), on the other hand, OBJ1 can be written to Window1  
5 without waiting for the end of decode period (2). In such a case, decode\_duration is not simply a sum of decode period (2) and write period (3). Let write period (31) denote a time required for writing OBJ1 to Window1 and write period (32) denote a time required for writing OBJ2 to Window2. FIG. 19B  
10 shows a case where decode period (2) is longer than a sum of clear period (1) and write period (31). In this case, decode\_duration is a sum of decode period (2) and write period (32).

FIG. 19C shows a case where a sum of clear period (1) and write period (31) is longer than decode period (2). In  
15 this case, decode\_duration is a sum of clear period (1), write period (31), and write period (32).

The size of the Graphics Plane is fixed according to a player model. Also, sizes and numbers of Windows and ODSS  
20 are set in advance at the time of authoring. Hence decode\_duration can be calculated as one of the sum of clear period (1) and write period (3), the sum of decode period (2) and write period (3), the sum of decode period (2) and write period (32), and the sum of clear period (1), write  
25 period (31), and write period (32). By setting the PTS of the PCS based on such calculated decode\_duration, graphics can be synchronized with picture data with high accuracy. Such accurate synchronous control is achieved by defining

Windows and restricting clearing and rendering operations within the Windows. Thus, the introduction of the concept "Window" in authoring is of great significance.

The following explains how a DTS and a PTS of the WDS in DS<sub>n</sub> are set. The DTS of the WDS is set so as to satisfy the following formula:

$$DTS(DS_n[WDS]) \geq DTS(DS_n[PCS])$$

10        The PTS of the WDS specifies a deadline for starting writing to the Graphics Plane. Since writing to the Graphics Plane is restricted to a Window, the time to start writing to the Graphics Plane can be determined by subtracting a time required for rendering on all Windows from the time shown  
15 by the PTS of the PCS. Let  $\sum SIZE(WDS.WIN[i])$  be a total size of Windows[i]. Then a time required for clearing and rendering on all Windows[i] is  $\sum SIZE(WDS.WIN[i]) // 256,000,000$ . Expressing this time with the accuracy of 90,000KHz yields  $90,000 \times \sum SIZE(WDS.WIN[i]) // 256,000,000$ .

20        Accordingly, the PTS of the WDS can be calculated as follows:

$$PTS(DS_n[WDS]) = PTS(DS_n[PCS]) - 90,000 \times \sum SIZE(WDS.WIN[i]) // 256,000,000$$

25

Since the PTS of the WDS shows the deadline, the writing to the Graphics Plane can be launched earlier than the time shown by this PTS. Which is to say, once decoding of one ODS

belonging to one of two Windows has completed, a graphics Object obtained by the decoding can be immediately written to the Window as shown in FIG. 19.

Thus, a Window can be allocated to a desired point on  
5 the reproduction time axis of the AV Clip, using the DTS and the PTS of the WDS. This completes the explanation on the DTS and PTS of each of the PCS and the WDS in DS<sub>n</sub>.

The following explains a forward reference by a PCS. A forward reference is a type of reproduction control that  
10 references a graphics Object which has already been stored in the reproduction apparatus 200. FIG. 20 shows forward reference PCSs. The drawing shows three DSs, i.e. DS<sub>n</sub>, DS<sub>n+1</sub>, and DS<sub>n+2</sub>. PCSs of DS<sub>n+1</sub> and DS<sub>n+2</sub> are forward reference PCSs. Arrows yy1 and yy2 indicate forward references made by these  
15 PCSs. Graphics Objects defined in ODS#1 to ODS#v in DS<sub>n</sub> are forward-referenced by these PCSs. Here, DS<sub>n</sub> contains a plurality of graphics Objects, i.e. ODS#1 to ODS#u and ODS#u+1 to ODS#v. Of these graphics Objects, ODS#1 to ODS#u are referenced by a PCS of DS<sub>n</sub>, but ODS#u+1 to ODS#v are not  
20 referenced by the PCS of DS<sub>n</sub>. These graphics Objects not referenced by the PCS of DS<sub>n</sub> are forward-referenced by the PCSs of DS<sub>n+1</sub> and DS<sub>n+2</sub>.

Such a graphics Object forward-referenced by a PCS in one DS has already been stored in the reproduction apparatus  
25 200, so that there is no need to wait for decoding of an ODS. This being so, by feeding only a PCS into the reproduction apparatus 200, display control based on that PCS can be carried out. Since the display control is carried out promptly when

the PCS is fed into the reproduction apparatus 200, a graphics update of replacing existing graphics with new graphics can be performed with a short time interval. Repeating such a short-interval graphics update makes it possible to realize  
5 display control of moving graphics smoothly as the reproduction of the moving picture progresses. Two description examples of forward reference PCSs are given below.

A description example of forward reference PCSs for  
10 realizing a display effect of moving graphics on a screen is explained first. FIG. 21A shows an Epoch having such a display effect. This Epoch is made up of nine DSs (DS0 to DS8). DS0, the first DS of the Epoch, includes a PCS, a PDS, and an ODS. The ODS in DS0 defines a subtitle "My heart is  
15 fluttering" shown in FIG. 22A, and has object\_id=1. Meanwhile, DS1 to DS8 which follow DS0 each include only a PCS.

FIG. 21B shows the composition\_object fields and PTSs of the PCSs in DS1 to DS8. As illustrated, the PCSs in DS1 to DS8 designate the graphics Object specified by  
20 object\_id\_ref=1 to be displayed at respective coordinates (x1,y1), (x2,y2), (x3,y3), ... , (x8,y8) specified by the object\_horizontal\_position and object\_vertical\_position fields. FIG. 22B shows positions of coordinates (x1,y1), (x2,y2), (x3,y3), ... , (x8,y8) in a coordinate system defined  
25 by a Window. As can be understood from the drawing, coordinates (x1,y1), (x2,y2), (x3,y3), ... , (x8,y8) lie on a wavy line. Coordinates (x1,y1), (x2,y2), (x3,y3), ... , (x8,y8) are set so that the graphics Object stays within the

Window defined by the WDS. This is because the synchronization between the graphics display of the graphics stream and the video display of the video stream cannot be established if the graphics Object is not contained within the Window.

5 In FIG. 21B, the PTSs of the PCSs in DS1 to DS8 designate times  $t_1, t_2, t_3, \dots, t_8$ , on the reproduction time axis of the video stream, at which the graphics Object is to be displayed at respective coordinates  $(x_1, y_1), (x_2, y_2), (x_3, y_3), \dots, (x_8, y_8)$ .

10 FIG. 23 shows a display effect when DS0 to DS8 having the above PCSs are sequentially fed into the reproduction apparatus 200. At  $t_1$  on the reproduction time axis of the video stream, DS1 is fed into the reproduction apparatus 200, and as a result the graphics is displayed at coordinates  $(x_1, y_1)$  within the Window. At  $t_4$ , DS4 is fed into the reproduction  
15 apparatus 200, and as a result the graphics is displayed at coordinates  $(x_4, y_4)$ . At  $t_6$ , DS6 is fed into the reproduction apparatus 200, and as a result the graphics is displayed at coordinates  $(x_6, y_6)$ . At  $t_8$ , DS8 is fed into the reproduction  
20 apparatus 200, and as a result the graphics is displayed at coordinates  $(x_8, y_8)$ . Since these coordinates  $(x_1, y_1), (x_4, y_4), (x_6, y_6)$ , and  $(x_8, y_8)$  lie on a wavy line, the graphics will end up tracing the wavy line as shown in FIG. 24.

Thus, when such DSs including PCSs which each have  
25 specified object\_horizontal\_position and object\_vertical\_position field values are sequentially fed into the reproduction apparatus 200, the reproduction apparatus 200 displays the graphics Object already stored

in the Object Buffer in accordance with these PCSs. Since the position of the graphics can be changed just by feeding the control information into the reproduction apparatus 200, quick movements of graphics on the screen can be achieved.

5        When feeding such DSs into the reproduction apparatus 200, a new PCS may be written over an existing PCS. This allows the reproduction apparatus 200 to hold only a newest PCS, even if there are tens or hundreds of PCSs showing display coordinates of graphics for smooth movement. In this way,  
10       the memory occupancy in the reproduction apparatus 200 can be minimized.

      A Palette-only Display Update is explained next, as another description example of forward reference PCSs. FIG. 25 shows a series of DSs for realizing a Palette-only Display  
15       Update. In the drawing, the first level shows the series of DSs (DS0, DS1, DS2, and DS3) for the Palette-only Display Update. DS0 has a PCS, four PDSs (PDS0, PDS1, PDS2, and PDS3), and an ODS. DS2, DS3, and DS4 that follow DS0 each have only a PCS.

20       The ODS in DS0 defines a subtitle "I will never forget", as indicated by guidelines hvl. The words "I", "will", "never", and "forget" are each constituted by a plurality of pieces of run-length data (indicated by rectangles shown in FIG. 25). Run-length data constituting "I" has Pixel Code 0.  
25       Run-length data constituting "will" has Pixel Code 1.  
      Run-length data constituting "never" has Pixel Code 2.  
      Run-length data constituting "forget" has Pixel Code 3.

      FIG. 26A shows the four PDSs in DS0.

PDS0 which is the first PDS in DS0 (on the first level) has palette\_id=0, and assigns a red color to Pixel Code 0 and a white color to Pixel Codes 1 to 3.

5 PDS1 which is the second PDS in DS0 (on the second level) has palette\_id=1, and assigns the red color to Pixel Codes 0 and 1 and the white color to Pixel Codes 2 and 3.

PDS2 which is the third PDS in DS0 (on the third level) has palette\_id=2, and assigns the red color to Pixel Codes 0, 1, and 2 and the white color to Pixel Code 3.

10 PDS3 which is the fourth PDS in DS0 (on the fourth level) has palette\_id=3, and assigns the red color to Pixel Codes 0 to 3.

FIG. 26B show descriptions of the PCSs in DS0 to DS3.

The PCS in DS0 (on the first level) designates display  
15 control to be performed using a graphics Object specified by object\_id\_ref=1. This PCS has palette\_update\_flag=0 and palette\_id\_ref=0. Accordingly, when DS0 is fed into the reproduction apparatus 200, the graphics Object shown by the ODS in DS0 is displayed using the PDS specified by palette\_id=0.

20 The PCS in DS1 (on the second level) designates display control to be performed using the graphics Object specified by object\_id\_ref=1. This PCS has palette\_update\_flag=1 and palette\_id\_ref=1. Accordingly, when DS1 is fed into the reproduction apparatus 200, the display of the graphics Object  
25 is updated using the PDS specified by palette\_id=1.

The PCS in DS2 (on the third level) designates display control to be performed using the graphics Object specified by object\_id\_ref=1. This PCS has palette\_update\_flag=1 and

palette\_id\_ref=2. Accordingly, when DS2 is fed into the reproduction apparatus 200, the display of the graphics Object is updated using the PDS specified by palette\_id=2.

The PCS in DS3 (on the fourth level) designates display control to be performed using the graphics Object specified by object\_id\_ref=1. This PCS has palette\_update\_flag=1 and palette\_id\_ref=3. Accordingly, when DS3 is fed into the reproduction apparatus 200, the display of the graphics Object is updated using the PDS specified by palette\_id=3. By setting the PCSs in DS0 to DS3 in this way, it is possible to repeatedly update the graphics Object belonging to DS0 using different palette data.

FIG. 27 shows a display effect achieved when these four DSs are sequentially fed into the reproduction apparatus 200. When DS0 is fed into the reproduction apparatus 200, the subtitle "I will never forget" is displayed with the word "I" being colored in red. When DS1 is fed into the reproduction apparatus 200, the word "will" turns red. When DS2 is fed into the reproduction apparatus 200, the word "never" turns red. When DS3 is fed into the reproduction apparatus 200, the word "forget" turns red, as a result of which the entire subtitle "I will never forget" is displayed in red. Thus, the words constituting the subtitle "I will never forget" change from white to red one by one beginning with the leftmost word, as the DSs are sequentially fed from the BD-ROM 100 to the reproduction apparatus 200. This produces a display effect of changing a subtitle in color as the reproduction of the audio stream progresses.

Note that the data structures of DSs (PCS, WDS, PDS, and ODS) explained above are instances of class structures written in a programming language. The author writes the class structures according to the syntax defined in the Blu-ray Disc Read-Only Format, to create these data structures on the BD-ROM 100. This completes the explanation on the recording medium according to the first embodiment of the present invention. The following explains a reproduction apparatus according to the first embodiment of the present invention. FIG. 28 shows an internal construction of the reproduction apparatus 200. The reproduction apparatus 200 is manufactured based on this internal construction. The reproduction apparatus 200 is roughly made up of three parts that are a system LSI, a drive device, and a microcomputer system. The reproduction apparatus 200 can be manufactured by mounting these parts on a cabinet and substrate of the apparatus. The system LSI is an integrated circuit including various processing units for achieving the functions of the reproduction apparatus 200. The reproduction apparatus 200 includes a BD drive 1, a Read Buffer 2, a PID filter 3, Transport Buffers 4a, 4b, and 4c, a peripheral circuit 4d, a Video Decoder 5, a Video Plane 6, an Audio Decoder 7, a Graphics Plane 8, a CLUT unit 9, an adder 10, and a Graphics Decoder 12. The Graphics Decoder 12 includes a Coded Data Buffer 13, a peripheral circuit 13a, a Stream Graphics Processor 14, an Object Buffer 15, a Composition Buffer 16, and a Graphics Controller 17.

The BD drive 1 performs loading, reading, and ejecting

of the BD-ROM 100. The BD drive 1 accesses to the BD-ROM 100.

The Read Buffer 2 is a FIFO (first-in first-out) memory. Accordingly, TS packets read from the BD-ROM 100 are removed from the Read Buffer 2 in the same order as they arrive.

5        The PID filter 3 performs filtering on TS packets output from the Read Buffer 2. In more detail, the PID filter 3 passes only TS packets having predetermined PIDs to the Transport Buffers 4a, 4b, and 4c. There is no buffering inside the PID filter 3. Accordingly, TS packets entering the PID filter  
10    3 are instantaneously written to the Transport Buffers 4a, 4b, and 4c.

The Transport Buffers 4a, 4b, and 4c are FIFO memories for storing TS packets output from the PID filter 3. A speed at which a TS packet is read from the Transport Buffer 4a  
15    is denoted by transfer rate Rx.

The peripheral circuit 4d has a wired logic for converting TS packets read from the Transport Buffer 4a to functional Segments. The functional Segments are then stored in the Coded Data Buffer 13.

20        The Video Decoder 5 decodes TS packets output from the PID filter 3 to obtain uncompressed pictures, and writes them to the Video Plane 6.

The Video Plane 6 is a plane memory for a moving picture.

The Audio Decoder 7 decodes TS packets output from the  
25    PID filter 3, and outputs uncompressed audio data.

The Graphics Plane 8 is a plane memory having a memory area of one screen, and is capable of storing uncompressed graphics of one screen.

The CLUT unit 9 converts index colors of the uncompressed graphics on the Graphics Plane 8, based on Y, Cr, and Cb values shown in a PDS.

5       The adder 10 multiplies the uncompressed graphics converted by the CLUT unit 9, by a T value (transparency) shown in the PDS. The adder 10 then performs addition for corresponding pixels in the resulting uncompressed graphics and the uncompressed picture data on the Video Plane 6, and outputs a resultant image.

10       The Graphics Decoder 12 decodes a graphics stream to obtain uncompressed graphics, and writes the uncompressed graphics to the Graphics Plane 8 as graphics Objects. As a result of decoding the graphics stream, subtitles and menus appear on the screen.

15       This Graphics Decoder 12 executes pipeline processing, by reading a graphics Object belonging to DS<sub>n</sub> from the Object Buffer 15 whilst simultaneously writing a graphics Object belonging to DS<sub>n</sub>+1 to the Object Buffer 15.

20       The Graphics Decoder 12 includes the Coded Data Buffer 13, the peripheral circuit 13a, the Stream Graphics Processor 14, the Object Buffer 15, the Composition Buffer 16, and the Graphics Controller 17.

25       The Coded Data Buffer 13 is used for storing functional Segments together with DTSSs and PTSSs. Such functional Segments are obtained by removing a TS packet header and a PES packet header from each TS packet stored in the Transport Buffer 4a and arranging remaining payloads in sequence. DTSSs and PTSSs contained in the removed TS packet headers and PES

packet headers are stored in the Coded Data Buffer 13 in correspondence with the functional Segments.

The peripheral circuit 13a has a wired logic for transferring data from the Coded Data Buffer 13 to the Stream Graphics Processor 14 and transferring data from the Coded Data Buffer 13 to the Composition Buffer 16. In more detail, when the current time reaches a DTS of an ODS, the peripheral circuit 13a transfers the ODS from the Coded Data Buffer 13 to the Stream Graphics Processor 14. Also, when the current time reaches a DTS of a PCS or a PDS, the peripheral circuit 13a transfers the PCS or the PDS from the Coded Data Buffer 13 to the Composition Buffer 16.

The Stream Graphics Processor 14 decodes the ODS to obtain uncompressed graphics having index colors, and transfers the uncompressed graphics to the Object Buffer 15 as a graphics Object. The decoding by the Stream Graphics Processor 14 is instantaneous, and the graphics Object obtained by the decoding is temporarily stored in the Stream Graphics Processor 14. Though the decoding by the Stream Graphics Processor 14 is instantaneous, the transfer of the graphics Object from the Stream Graphics Processor 14 to the Object Buffer 15 is not instantaneous. This is because transfer to the Object Buffer 15 is performed at a transfer rate of 128Mbps in the player model of the Blu-ray Disc Read-Only Format. An end of transfer of all graphics Objects belonging to a DS to the Object Buffer 15 is shown by a PTS of an END in the DS. Therefore, processing of the next DS will not be started until the time shown by the PTS of the

END. Transfer of a graphics Object obtained by decoding each ODS to the Object Buffer 15 starts at a time shown by a DTS of the ODS and ends at a time shown by a PTS of the ODS.

If a graphics Object of DS<sub>n</sub> and a graphics Object of  
5 DS<sub>n+1</sub> have different object\_ids, the Stream Graphics  
Processor 14 writes the two graphics Objects in different  
storage areas of the Object Buffer 15. This allows pipeline  
presentation of the graphics Objects, without the graphics  
Object of DS<sub>n</sub> being overwritten by the graphics Object of  
10 DS<sub>n+1</sub>. If the graphics Object of DS<sub>n</sub> and the graphics Object  
of DS<sub>n+1</sub> have the same object\_id, on the other hand, the Stream  
Graphics Processor 14 writes the graphics Object of DS<sub>n+1</sub>  
to a storage area in the Object Buffer 15 in which the graphics  
Object of DS<sub>n</sub> is stored, so as to overwrite the graphics Object  
15 of DS<sub>n</sub>. In this case, pipeline processing is not performed.  
Also, a DS may include ODSs which are referenced by a PCS  
of the DS and ODSs which are not referenced by the PCS. The  
Stream Graphics Processor 14 sequentially decodes not only  
the ODSs referenced by the PCS but also the ODSs not referenced  
20 by the PCS, and stores graphics obtained by the decoding to  
the Object Buffer 15.

The Object Buffer 15 corresponds to a pixel buffer in  
ETSI EN 300 743. Graphics Objects decoded by the Stream  
Graphics Processor 14 are stored in the Object Buffer 15.  
25 A size of the Object Buffer 15 needs to be twice or four times  
as large as that of the Graphics Plane 8. This is because  
the Object Buffer 15 needs to be capable of storing twice  
or four times as much graphics as the Graphics Plane 8 in

order to achieve scrolling.

The Composition Buffer 16 is used for storing a PCS and a PDS. When active periods of PCSs in DS<sub>n</sub> and DS<sub>n+1</sub> overlap, the Composition Buffer 16 stores the PCSs of both DS<sub>n</sub> and  
5 DS<sub>n+1</sub>.

The Graphics Controller 17 decodes the PCSs in the Composition Buffer 16. Based on a decoding result, the Graphics Controller 17 writes a graphics Object of DS<sub>n+1</sub> to the Object Buffer 15, while reading a graphics Object of DS<sub>n</sub>  
10 from the Object Buffer 15 and presenting it for display. The presentation by the Graphics Controller 17 is performed at a time shown by a PTS of the PCS in DS<sub>n</sub>.

To produce a screen composition using a PCS, the Graphics Controller 17 performs the following processing. The  
15 Graphics Controller 17 reads an `object_id_ref` which is a reference value of an identifier of a graphics Object, from the PCS. The Graphics Controller 17 takes out one part of the graphics Object that is defined by an  
20 `object_cropping_horizontal_position`, an `object_cropping_vertical_position`, an `object_cropping_width`, and an `object_cropping_height`. The Graphics Controller 17 writes the taken part on the Graphics Plane 8 at a position shown by an `object_horizontal_position` and an `object_vertical_position`. If the graphics Object  
25 specified by the reference value belongs to the same DS as the PCS, the above writing to the Graphics Plane 8 cannot be performed until after a corresponding ODS in that DS is decoded.

On the other hand, when a composition\_state of the PCS shows Normal Case, the graphics Object has already been decoded and stored in the Object Buffer 15. Accordingly, the above writing to the Graphics Plane 8 can be performed without waiting  
5 for decoding of an ODS.

To effect a Palette-only Display Update, the Graphics Controller 17 performs the following processing. Once a DS has been read from the BD-ROM 100, the Graphics Controller 17 judges whether a palette\_update\_flag of a PCS in the DS  
10 is "1". If the palette\_update\_flag is "1", the Graphics Controller 17 instructs the CLUT unit 9 to perform pixel value conversion using palette data specified by a palette\_id of the PCS. The Graphics Controller 17 then reads a graphics Object from the Object Buffer 15 and writes it to the Graphics  
15 Plane 8. Thus, a graphics update can be carried out just by setting the palette data in the CLUT unit 9.

Recommended transfer rates and buffer sizes for realizing the PID filter 3, the Transport Buffers 4a, 4b, and 4c, the Graphics Plane 8, the CLUT unit 9, the Coded Data  
20 Buffer 13, the Stream Graphics Processor 14, the Object Buffer 15, the Composition Buffer 16, and the Graphics Controller 17 are given below. FIG. 29 shows transfer rates Rx, Rc, and Rd and sizes of the Graphics Plane 8, the Transport Buffer 4a, the Coded Data Buffer 13, and the Object Buffer 15.

25       Transferrate Rc (Pixel Composition Rate) from the Object Buffer 15 to the Graphics Plane 8 is a highest transfer rate in the reproduction apparatus 200, and is calculated as 256Mbps (=500Kbytes×29.97×2) from a Window size and a frame rate.

Transfer rate  $R_d$  (Pixel Decoding Rate) from the Stream Graphics Processor 14 to the Object Buffer 15 does not need to coincide with the frame rate unlike  $R_c$ , and may be  $1/2$  or  $1/4$  of  $R_c$ . Therefore, transfer rate  $R_d$  is 128Mbps or 64Mbps.

5        Transfer rate  $R_x$  (Transport Buffer Leak Rate) from the Transport Buffer 4a to the Coded Data Buffer 13 is a transfer rate of ODSs in a compressed state. Accordingly, transfer rate  $R_x$  can be calculated by multiplexing  $R_d$  by a compression rate of ODSs. For example, when the compression rate is 25%,  
10    transfer rate  $R_x$  is 16Mbps ( $=64\text{Mbps} \times 25\%$ ).

These transfer rates and buffer sizes are merely shown as minimum standards, and transfer rates and buffer sizes greater than those shown in FIG. 29 are equally applicable.

15        In the above constructed reproduction apparatus 200, the construction elements perform processing in a pipeline.

FIG. 30 is a timing chart showing pipeline processing performed in the reproduction apparatus 200. In the drawing, the fifth level shows a DS on the BD-ROM 100. The fourth level shows write periods of a PCS, a WDS, a PDS, ODSs, and an END  
20    to the Coded Data Buffer 13. The third level shows decode periods of the ODSs by the Stream Graphics Processor 14. The second level shows storage contents of the Composition Buffer 16. The first level shows operations of the Graphics Controller 17.

25        DTSSs of ODS1 and ODS2 show  $t_{31}$  and  $t_{32}$  respectively. Therefore, ODS1 and ODS2 need to be buffered in the Coded Data Buffer 13 by  $t_{31}$  and  $t_{32}$  respectively. This being so, writing of ODS1 to the Coded Data Buffer 13 is completed by

t31 at which decode period dp1 begins, and writing of ODS2 to the Coded Data Buffer 13 is completed by t32 at which decode period dp2 begins.

Meanwhile, PTSs of ODS1 and ODS2 show t32 and t33  
5 respectively. Accordingly, decoding of ODS1 by the Stream Graphics Processor 14 is completed by t32, and decoding of ODS2 by the Stream Graphics Processor 14 is completed by t33. Thus, an ODS is buffered in the Coded Data Buffer 13 by a time shown by a DTS of the ODS, and the buffered ODS is decoded  
10 and transferred to the Object Buffer 15 by a time shown by a PTS of the ODS.

On the first level, cd1 denotes a time period needed for the Graphics Controller 17 to clear the Graphics Plane 8, and td1 denotes a time period needed for the Graphics  
15 Controller 17 to write graphics obtained in the Object Buffer 15 to the Graphics Plane 8. A PTS of the WDS shows a deadline for starting writing the graphics. A PTS of the PCS shows a time at which the writing of the graphics to the Graphics Plane 8 ends and the written graphics is presented for display.  
20 Therefore, uncompressed graphics of one screen is obtained on the Graphics Plane 8 at the time shown by the PTS of the PCS. The CLUT unit 9 performs color conversion on the uncompressed graphics, and the adder 10 overlays the graphics on an uncompressed picture stored on the Video Plane 6. This  
25 produces a resultant image.

In the Graphics Decoder 12, the Stream Graphics Processor 14 continues decoding while the Graphics Controller 17 is clearing the Graphics Plane 8. As a result of such pipeline

processing, graphics can be displayed speedily.

FIG. 30 shows an example when the clearing of the Graphics Plane 8 ends before the decoding of the ODSs. FIG. 31, on the other hand, is a timing chart showing pipeline processing  
5 when the decoding of the ODSs ends before the clearing of the Graphics Plane 8. In this case, upon completion of the decoding of the ODSs, the graphics obtained by the decoding cannot yet be written to the Graphics Plane 8. Only after the clearing of the Graphics Plane 8 is completed, the graphics  
10 can be written to the Graphics Plane 8.

FIG. 32 is a timing chart showing changes in buffer occupancy in the reproduction apparatus 200. In the drawing, the first to fourth levels show changes in occupancy of the Graphics Plane 8, the Object Buffer 15, the Coded Data Buffer  
15 13, and the Composition Buffer 16, respectively. These changes are shown in the form of a line graph in which the horizontal axis represents time and the vertical axis represents occupancy.

The fourth level shows changes in occupancy of the  
20 Composition Buffer 16. As illustrated, the changes in occupancy of the Composition Buffer 16 include monotone increase Vf0 with which the PCS output from the Coded Data Buffer 13 is stored.

The third level shows changes in occupancy of the Coded  
25 Data Buffer 13. As illustrated, the changes in occupancy of the Coded Data Buffer 13 include monotone increases Vf1 and Vf2 with which ODS1 and ODS2 are stored, and monotone decreases Vg1 and Vg2 with which ODS1 and ODS2 are sequentially read

by the Stream Graphics Processor 14. Slopes of monotone increases  $Vf1$  and  $Vf2$  are based on transfer rate  $Rx$  from the Transport Buffer 4a to the Coded Data Buffer 13, whereas monotone decreases  $Vg1$  and  $Vg2$  are instantaneous since  
5 decoding by the Stream Graphics Processor 14 is performed instantaneously. Which is to say, the Stream Graphics Processor 14 decodes each ODS instantaneously and holds uncompressed graphics obtained by the decoding. Since transfer rate  $Rd$  from the Stream Graphics Processor 14 to  
10 the Object Buffer 15 is 128Mbps, the occupancy of the Object Buffer 15 increases at 128Mbps.

The second level shows changes in occupancy of the Object Buffer 15. As illustrated, the changes in occupancy of the Object Buffer 15 include monotone increases  $Vh1$  and  $Vh2$  with  
15 which the graphics Objects of ODS1 and ODS2 output from the Stream Graphics Processor 14 are stored. Slopes of monotone increases  $Vh1$  and  $Vh2$  are based on transfer rate  $Rd$  from the Stream Graphics Processor 14 to the Object Buffer 15. A decode period of each of ODS1 and ODS2 corresponds to a time period  
20 in which a monotone decrease occurs on the third level and a monotone increase occurs on the second level. The beginning of the decode period is shown by a DTS of the ODS, whereas the end of the decode period is shown by a PTS of the ODS. Once the uncompressed graphics Object has been transferred  
25 to the Object Buffer 15 by the time shown by the PTS of the ODS, the decoding of the ODS is complete. It is essential for the uncompressed graphics Object to be stored in the Object Buffer 15 by the time shown by the PTS of the ODS. As long

as this is satisfied, the monotone decrease and the monotone increase in the decode period are not limited to those shown in FIG. 32.

The first level shows changes in occupancy of the Graphics Plane 8. As illustrated, the changes in occupancy of the Graphics Plane 8 include monotone increase Vf3 with which the graphics Objects output from the Object Buffer 15 are stored. A slope of monotone increase Vf3 is based on transfer rate Rc from the Object Buffer 15 to the Graphics Plane 8. The end of monotone increase Vf3 is shown by the PTS of the PCS.

The graph such as the one shown in FIG. 32 can be created through the use of the DTSS and PTSS of the ODSs, the DTS and the PTS of the PCS, and the buffer sizes and transfer rates shown in FIG. 29. Such a graph allows the author to grasp how the buffer states change when the AV Clip on the BD-ROM 100 is reproduced.

These changes of the buffer states can be adjusted by rewriting DTSSs and PTSSs. Therefore, it is possible for the author to prevent the occurrence of such a decoding load that exceeds specifications of a decoder of the reproduction apparatus 200, or to prevent a buffer overflow during reproduction. This makes it easier to implement hardware and software when developing the reproduction apparatus 200. This completes the explanation on the internal construction of the reproduction apparatus 200.

The following explains how to implement the Graphics Decoder 12. The Graphics Decoder 12 can be realized by having

a general-purpose CPU execute a program for performing an operation shown in FIG. 33. An operation of the Graphics Decoder 12 is explained below, with reference to FIG. 33.

FIG. 33 is a flowchart showing an operation of loading  
5 a functional Segment. In the drawing, SegmentK is a variable indicating a Segment (PCS, WDS, PDS, or ODS) which belongs to a DS and is read during reproduction of the AV Clip, and an ignore flag indicates whether SegmentK is to be ignored or loaded. In this flowchart, after the ignore flag is reset  
10 to 0 (S20), a loop of steps S21 to S24 and S27 to S31 is performed for each SegmentK (S25 and S26).

Step S21 judges whether SegmentK is a PCS. If SegmentK is a PCS, the operation proceeds to step S27.

Step S22 judges whether the ignore flag is 0 or 1. If  
15 the ignore flag is 0, the operation proceeds to step S23. If the ignore flag is 1, the operation proceeds to step S24. In step S23, SegmentK is loaded to the Coded Data Buffer 13.

If the ignore flag is 1 (S22:NO), SegmentK is ignored (S24). This leads to the negative judgement on all functional  
20 Segments belonging to the DS in step S22, as a result of which the functional Segments of the DS are all ignored.

Thus, the ignore flag indicates whether SegmentK is to be ignored or loaded. Steps S27 to S31 and S34 to S35 are performed to set this ignore flag.

25 Step S27 judges whether a composition\_state field of the PCS shows Acquisition Point. If the composition\_state field shows Acquisition Point, the operation proceeds to step S28. If the composition\_state field shows Epoch Start or

Normal Case, the operation proceeds to step S31.

Step S28 judges whether an immediately preceding DS exists in any of the buffers (the Coded Data Buffer 13, the Stream Graphics Processor 14, the Object Buffer 15, and the Composition Buffer 16) in the Graphics Decoder 12. The immediately preceding DS does not exist in the Graphics Decoder 12 if a skip operation is performed. In this case, the display needs to be started from the Acquisition Point DS, so that the operation proceeds to step S30 (S28:NO).

10 In step S30, the ignore flag is set to 0, and the operation proceeds to step S22.

On the other hand, the immediately preceding DS exists in the Graphics Decoder 12 if normal reproduction is performed. In this case, the operation proceeds to step S29 (S28:YES).  
15 In step S29, the ignore flag is set to 1, and the operation proceeds to step S22.

Step S31 judges whether the composition\_state field shows Normal Case. If the composition\_state field shows Normal Case, the operation proceeds to step S34. If the composition\_state field shows Epoch Start, the operation proceeds to step S30 where the ignore flag is set to 0. Step S34 is the same as step S28, and judges whether the immediately preceding DS exists in the Graphics Decoder 12. If the immediately preceding DS exists, the ignore flag is set to  
20 0 (S30). Otherwise, the ignore flag is set to 1, because  
25 enough functional Segments for composing one screen of graphics cannot be obtained (S35). In this way, when the immediately preceding DS does not exist in the Graphics Decoder

12, the functional Segments of the Normal Case DS are ignored.

The following gives a specific example of loading DSs, with reference to FIG. 34. In FIG. 34, three DSs (DS1, DS10, and DS20) are multiplexed with video. A composition\_state field of DS1 shows Epoch Start, a composition\_state field of DS10 shows Acquisition Point, and a composition\_state field of DS20 shows Normal Case.

Suppose a skip operation is performed on picture data pt10 in an AV Clip in which these three DSs are multiplexed with video, as indicated by arrow am1. In such a case, DS10 which is closest to pt10 is subjected to the operation shown in FIG. 33. The composition\_state field of DS10 shows Acquisition Point (S27:YES), but the immediately preceding DS (DS1) does not exist in the Coded Data Buffer 13 (S28:NO). Accordingly, the ignore flag is set to 0 (S30). As a result, DS10 is loaded to the Coded Data Buffer 13 as indicated by arrow md1 in FIG. 35. Suppose, on the other hand, a skip operation is performed on picture data which is located after DS10, as indicated by arrow am2 in FIG. 34. In this case, DS20 is a Normal Case DS, and the immediately preceding DS (DS10) does not exist in the Coded Data Buffer 13. Accordingly, DS20 is ignored, as indicated by arrow md2 in FIG. 35.

FIG. 37 shows how DS1, DS10, and DS20 are loaded when normal reproduction is performed as shown in FIG. 36. Of the three DSs, DS1 which is an Epoch Start DS is loaded to the Coded Data Buffer 13, as indicated by arrow rd1 (S23). However, the ignore flag is set to 1 for DS10 which is an Acquisition Point DS (S29), so that the functional Segments of DS10 are

not loaded to the Coded Data Buffer 13 but ignored, as indicated by arrow rd2 (S24). Meanwhile, DS20 which is a Normal Case DS is loaded to the Coded Data Buffer 13, as indicated by arrow rd3 (S23).

5       The following explains an operation of the Graphics Controller 17. FIGS. 38 to 40 are flowcharts showing the operation of the Graphics Controller 17.

Steps S41 to S44 constitute a main routine, where an event specified by any of steps S41 to S44 is waited.

10       In FIG. 38, step S41 judges whether the current reproduction time is a DTS of a PCS. If so, steps S45 to S53 are performed.

Step S45 judges whether a composition\_state field of the PCS shows Epoch Start. If so, the entire Graphics Plane 15 8 is cleared in step S46. Otherwise, a Window specified by a window\_horizontal\_position field, a window\_vertical\_position field, a window\_width field, and a window\_height field of a WDS is cleared in step S47.

Step S48 is performed after step S46 or S47, and judges 20 whether a PTS of arbitrary ODSx has passed. Clearing the entire Graphics Plane 8 takes a long time, so that decoding of ODSx may already be completed by the time the entire Graphics Plane 8 is cleared. Step S48 examines this possibility. If the PTS of ODSx has not passed, the operation returns to the 25 main routine. If the PTS of ODSx has passed, steps S49 to S51 are performed. Step S49 judges whether an object\_cropped\_flag field shows 0. If so, a graphics Object corresponding to ODSx is set to non-display (S50).

If the object\_cropped\_flag shows 1, the graphics Object  
cropped based on an object\_cropping\_horizontal\_position  
field, an object\_cropping\_vertical\_position field, a  
cropping\_width field, and a cropping\_height field is written  
5 to the Window on the Graphics Plane 8 at a position specified  
by an object\_horizontal\_position field and an  
object\_vertical\_position field (S51). In this way, the  
graphics Object is written to the Window.

Step S52 judges whether a PTS of another ODS (ODSy) has  
10 passed. If decoding of ODSy is completed during when the  
graphics Object of ODSx is being written to the Graphics Plane  
8, ODSy is set as ODSx (S53), and the operation returns to  
step S49. As a result, steps S49 to S51 are performed on ODSy.

In FIG. 39, step S42 judges whether the current  
15 reproduction time is a PTS of the WDS. If so, the operation  
proceeds to step S54, to judge whether the number of Windows  
is 1. If the number of Windows is 2, the operation returns  
to the main routine. If the number of Windows is 1, a loop  
of steps S55 to S59 is performed. In this loop, steps S57  
20 to S59 are performed for each of at most two graphics Objects  
to be displayed in the Window. Step S57 judges whether the  
object\_cropped\_flag field shows 0. If so, the graphics Object  
is set to non-display (S58).

If the object\_cropped\_flag field shows 1, the graphics  
25 Object cropped based on an  
object\_cropping\_horizontal\_position field, an  
object\_cropping\_vertical\_position field, a cropping\_width  
field, and a cropping\_height field is written to the Window

on the Graphics Plane 8 at a position specified by an  
object\_horizontal\_position field and an  
object\_vertical\_position field (S59). As a result of this  
loop, one or more graphics Objects are written to the Window.

5        Step S44 judges whether the current reproduction time  
is a PTS of the PCS. If so, the operation proceeds to step  
S60 to judge whether a palette\_update\_flag field shows 1.  
If so, a Palette identified by a palette\_id field is set to  
the CLUT unit 9 (S61). If the palette\_update\_flag field shows  
10    0, step S61 is skipped.

After this, the CLUT unit 9 performs color conversion  
of graphics on the Graphics Plane 8. The graphics is then  
overlaid on video (S62).

In FIG. 40, step S43 judges whether the current  
15    reproduction time is a PTS of an ODS. If so, the operation  
proceeds to step S63 to judge whether the number of Windows  
is 2. If the number of Windows is 1, the operation returns  
to the main routine.

Here, the judgements made in steps S43 and S63 have the  
20    following meaning. If the number of Windows is 2, two graphics  
Objects are displayed respectively in the two Windows. In  
such a case, each time decoding of one ODS is completed, a  
graphics Object obtained by the decoding needs to be written  
to the Graphics Plane 8 (see FIG. 19B). Therefore, if the  
25    current reproduction time is the PTS of the ODS and the number  
of Windows is 2, steps S64 to S66 are performed to write each  
individual graphics Object to the Graphics Plane 8. Step S64  
judges whether the object\_cropped\_flag field shows 0. If so,

the graphics Object is set to non-display (S65).

If the object\_cropped\_flag field shows 1, the graphics Object cropped based on an object\_cropping\_horizontal\_position field, an  
5 object\_cropping\_vertical\_position field, a cropping\_width field, and a cropping\_height field is written to a Window on the Graphics Plane 8 at a position specified by an object\_horizontal\_position field and an  
10 object\_vertical\_position field (S66). By repeating this process, two graphics Objects are written respectively to the two Windows.

#### (Second Embodiment)

The second embodiment of the present invention relates  
15 to a manufacturing process of the BD-ROM 100 explained in the first embodiment. FIG. 41 is a flowchart showing the manufacturing process of the BD-ROM 100.

The manufacturing process includes a material  
production step of recording video, sound, and the like (S201),  
20 an authoring step of creating an application format using an authoring device (S202), and a pressing step of creating an original master of the BD-ROM 100 and performing stamping and bonding to complete the BD-ROM 100 (S203).

In this manufacturing process, the authoring step  
25 includes steps S204 to S213.

In step S204, control information, Window definition information, Palette definition information, and graphics are generated. In step S205, the control information, the

Window definition information, the Palette definition information, and the graphics are converted to functional Segments. In step S206, a PTS of each PCS is set based on a time of a picture to be synchronized with. In step S207,  
5 a DTS[ODS] and a PTS[ODS] are set based on the PTS[PCS]. In step S208, a DTS[PCS], a PTS[PDS], a DTS[WDS], and a PTS[WDS] are set based on the DTS[ODS]. In step S209, changes in occupancy of each buffer in the player model are graphed. In step S210, a judgement is made as to whether the graphed  
10 changes satisfy constraints of the player model. If the judgement is in the negative, the DTS and PTS of each functional Segment are rewritten in step S211. If the judgement is in the affirmative, a graphics stream is generated in step S212, and the graphics stream is multiplexed with a video stream  
15 and an audio stream to form an AV Clip in step S213. After this, the AV Clip is adapted to the Blue-ray Disc Read-Only Format, to complete the application format.

(Modifications)

20        Though the present invention has been described by way of the above embodiments, the present invention is not limited to such. The present invention can be realized with any of modifications (A) to (P) below. The invention of each of the claims of this application includes extension and  
25 generalization of the above embodiments and their modifications below. The degree of extension and generalization depends upon the state of the art in the technical field of the present invention at the time when

the present invention was made.

(A) The above embodiments describe the case where the BD-ROM is used as the recording medium. Main features of the present invention, however, lie in a graphics stream recorded  
5 on the recording medium, which does not rely on physical characteristics of BD-ROMs. Therefore, the present invention is applicable to any recording medium that is capable of recording a graphics stream. Examples of such a recording medium include: an optical disc such as a DVD-ROM, a DVD-RAM,  
10 a DVD-RW, a DVD-R, a DVD+RW, a DVD+R, a CD-R, or a CD-RW; a magneto-optical disk such as a PD or an MO; a semiconductor memory card such as a CompactFlash card, a SmartMedia card, a Memory Stick card, a MultiMediaCard, or a PCMCIA card; a magnetic disk such as a flexible disk, SuperDisk, Zip, or  
15 Klik!; a removable hard disk drive such as ORB, Jaz, SparQ, SyJet, EZFley, or Microdrive, and a nonremovable hard disk drive.

(B) The above embodiments describe the case where the reproduction apparatus decodes an AV Clip on the BD-ROM and  
20 outputs the decoded AV Clip to the television. As an alternative, the reproduction apparatus may be equipped with only a BD drive, with the remaining construction elements being provided in the television. In this case, the reproduction apparatus and the television can be incorporated  
25 in a home network connected with an IEEE 1394 connector. The above embodiments describe the case where the reproduction apparatus is connected to the television, but the reproduction apparatus may instead be integrated with a display device.

Also, the reproduction apparatus may include only the system LSI (integrated circuit) which constitutes an essential part of processing. The reproduction apparatus and the integrated circuit are both an invention described in this specification.

5 Accordingly, regardless of whether the reproduction apparatus or the integrated circuit is concerned, an act of manufacturing a reproduction apparatus based on the internal construction of the reproduction apparatus described in the first embodiment is an act of working of the present invention.

10 Also, any act of assigning with charge (i.e. for sale) or without charge (i.e. as a gift), leasing, and importing the reproduction apparatus is an act of working of the present invention. Likewise, an act of offering for assignment or lease of the reproduction apparatus using storefront displays,

15 catalogs, or brochures is an act of working of the present invention.

(C) Information processing using the programs shown in the flowcharts is actually realized using hardware resources. Accordingly, the programs which describe the operational

20 procedures shown in the flowcharts are themselves an invention. The above embodiments describe the case where the programs are incorporated in the reproduction apparatus, but the programs can be used independently of the reproduction apparatus. Acts of working of the programs include (1) an

25 act of manufacturing, (2) an act of assigning with or without charge, (3) an act of leasing, (4) an act of importing, (5) an act of providing to the public via a bi-directional electronic communications network, and (6) an act of offering

for assignment or lease using storefront displays, catalogs, or brochures.

(D) The time elements of the steps which are executed in a time series in each of the flowcharts can be regarded  
5 as the necessary elements of the present invention. This being so, a reproduction method shown by these flowcharts is an invention. If the processing shown in each flowchart is carried out by performing the steps in a time series so as to achieve the intended aim and the intended effect, this  
10 is an act of working of the recording method of the present invention.

(E) When recording an AV Clip on the BD-ROM, an extension header may be added to each TS packet in the AV Clip. The extension header is called a TP\_extra\_header, includes an  
15 arrival\_time\_stamp and a copy\_permission\_indicator, and has a data length of 4 bytes. TS packets with TP\_extra\_headers (hereafter "EX TS packets") are grouped in units of 32 packets, and each group is written to three sectors. One group made up of 32 EX TS packets has 6,144 bytes ( $=32 \times 192$ ), which is  
20 equivalent to a size of three sectors that is 6144 bytes ( $=2048 \times 3$ ). The 32 EX TS packets contained in the three sectors are called an Aligned Unit.

In a home network connected with an IEEE 1394 connector, the reproduction apparatus transmits an Aligned Unit in the  
25 following manner. The reproduction apparatus removes a TP\_extra\_header from each of the 32 EX TS packets in the Aligned Unit, encrypts the body of each TS packet according to the DTCP Specification, and outputs the encrypted TS packets.

When outputting the TS packets, the reproduction apparatus inserts an isochronous packet between adjacent TS packets. A position where the isochronous packet is inserted is based on a time shown by an arrival\_time\_stamp of the TP\_extra\_header.

5 The reproduction apparatus outputs a DTCP\_descriptor, as well as the TS packets. The DTCP\_descriptor corresponds to a copy\_permission\_indicator in the TP\_extra\_header. With the provision of the DTCP\_descriptor indicating "copy prohibited", it is possible to prevent, when using the TS packets in the  
10 home network connected with the IEEE 1394 connector, the TS packets from being recorded to other devices.

(F) The above embodiments describe the case where an AV Clip of the Blu-ray Disc Read-Only Format is used as a digital stream, but the present invention can also be realized  
15 with a VOB (Video Object) of the DVD-Video Format or the DVD-Video Recording Format. The VOB is a program stream that complies with the ISO/IEC 13818-1 Standard and is obtained by multiplexing a video stream and an audio stream. Also, the video stream in the AV Clip may be an MPEG4 video stream  
20 or a WMV video stream. Further, the audio stream in the AV Clip may be a Linear PCM audio stream, a Dolby AC-3 audio stream, an MP3 audio stream, an MPEG-AAC audio stream, or a dts audio stream.

(G) The film described in the above embodiments may be  
25 obtained by encoding an analog image signal broadcast by analog broadcasting. Also, the film may be stream data made up of a transport stream broadcast by digital broadcasting.

Alternatively, an analog/digital image signal recorded

on a videotape may be encoded to obtain content. Also, an analog/digital image signal directly captured by a video camera may be encoded to obtain content. A digital work distributed by a distribution server is applicable too.

5       (H) Graphics Objects described in the above embodiments is run-length encoded raster data. Run-length encoding is used for compression/encoding of graphics Objects, because the run-length encoding is suitable for compression and decompression of subtitles. Subtitles have a property in that  
10 a continuous length of the same pixel value in a horizontal direction is relatively long. Therefore, by performing compression using run-length encoding, a high compression rate can be attained. In addition, run-length encoding reduces a load for decompression, and is therefore suitable  
15 for realizing decoding by software. Nevertheless, the use of run-length encoding for graphics Objects is not a limitation of the present invention. For example, graphics Objects may be PNG data. Also, graphics Objects may be vector data instead of raster data. Further, graphics Objects may be transparent  
20 patterns.

(I) Graphics of subtitles selected according to a language setting in the reproduction apparatus may be subjected to display effects of PCSSs. As a result, display effects achieved by using characters which are contained  
25 within the body of video in a conventional DVD can be realized with subtitle graphics displayed according to the language setting of the reproduction apparatus. This contributes to high practicality.

Also, subtitle graphics selected according to a display setting of the reproduction apparatus may be subjected to display effects of PCSs. For example, graphics of various display modes such as wide screen, pan and scan, and letterbox are recorded on the BD-ROM, and the reproduction apparatus selects one of these display modes according to a display setting of the television connected with the reproduction apparatus and displays corresponding graphics. Since the display effects of PCSs are applied to such graphics, viewability increases. As a result, display effects achieved by using characters which are contained within the body of video in a conventional DVD can be realized with subtitle graphics displayed according to the display setting. This contributes to high practicality.

(J) The first embodiment describes the case where transfer rate  $R_c$  from the Object Buffer to the Graphics Plane is set so as to clear the Graphics Plane and render graphics on a Window, which is 25% in size of the Graphics Plane, within one video frame. However, transfer rate  $R_c$  may be set so that the clearing and the rendering complete within a vertical blanking time. Suppose the vertical blanking time is 25% of  $1/29.97$  seconds. Then  $R_c$  is 1Gbps. By setting  $R_c$  in this way, graphics can be displayed smoothly.

Also, writing in sync with line scan can be used together with writing within a vertical blanking time. This enables subtitles to be displayed smoothly with  $R_c=256\text{Mbps}$ .

(K) The above embodiments describe the case where the reproduction apparatus includes the Graphics Plane.

Alternatively, the reproduction apparatus may include a line buffer for storing uncompressed pixels of one line. Since conversion to an image signal is performed for each horizontal row (line), conversion to an image signal can equally be performed with the line buffer.

(L) The above embodiments describe the case where graphics is character strings representing dialogs in a film, but the present invention is equally applicable to any graphics that is displayed in precise synchronization with video. Examples of such graphics include an illustration, a pattern, a cartoon character, and a symbol mark. Examples of such graphics also include a combination of figures, letters, and colors constituting a trademark, a national crest, a national flag, a national emblem, a public symbol or seal employed by a national government for supervision/certification, a crest, flag, or emblem of an international organization, or a mark of origin of a particular item.

(M) The first embodiment describes the case where a Window is provided on the top or bottom of the Graphics Plane, on an assumption that subtitles are displayed horizontally on the top or bottom of the screen. Instead, a Window may be provided on the left or right of the Graphics Plane, to display subtitles vertically on the left or right of the screen. This enables Japanese subtitles to be displayed vertically.

(O) The Graphics Decoder performs pipeline processing on  $DS_n$  and  $DS_{n+1}$ , when  $DS_n$  and  $DS_{n+1}$  belong to the same Epoch in the graphics stream. When  $DS_n$  and  $DS_{n+1}$  belong to different Epochs, on the other hand, the Graphics Decoder starts

processing  $DS_{n+1}$  after display of graphics of  $DS_n$  begins.

Also, there are two types of graphics streams, i.e., a Presentation graphics stream which is mainly intended to synchronize with video, and an Interactive graphics stream which is mainly intended to realize an interactive display. The Graphics Decoder performs pipeline processing of  $DS_n$  and  $DS_{n+1}$  when the graphics stream is a Presentation graphics stream, and does not perform pipeline processing when the graphics stream is an Interactive graphics stream.

(P) In the example shown in FIG. 20, graphics data referenced by a PCS in a DS is set before graphics data not referenced by the PCS in the DS. However, a plurality of sets of referenced graphics data and a plurality of sets of non-referenced graphics data may instead be arranged in a DS in an order specified by their object\_ids. Alternatively, the plurality of sets of referenced graphics data may be arranged in a scan line order. The scan line order referred to here is an order in which scanning is performed. In general, scanning is performed from the top left to bottom right of a screen. This being so, graphics data whose display coordinates lie at the top left of the screen is set before graphics data whose display coordinates lie at the bottom right of the screen. This accelerates presentation of graphics data.

The present invention can be modified as explained above. Nevertheless, the invention of each of the claims of this application reflects means for solving the technical problem encountered by the conventional techniques, so that the

technical scope of the invention according to the claims will not extend beyond the technical scope in which one skilled in the art acknowledges the technical problem. Hence the invention according to the claims substantially corresponds  
5 to the description of the specification.

#### Industrial Applicability

The above embodiments disclose the internal constructions of the recording medium and the reproduction  
10 apparatus to which the present invention relates, and the recording medium and the reproduction apparatus can be manufactured in volume based on the disclosed internal constructions. In other words, the recording medium and the reproduction apparatus are capable of being industrially  
15 manufactured. Hence the recording medium and the reproduction apparatus have industrial applicability.
